The Competitive Position of Illinois Coal in the Illinois Coal Market Area

WALTER H. VOSKUIL

CHAPTER I

A SURVEY OF THE MARKET FOR ILLINOIS COAL

ILLINOIS SUPPLIES COAL to seven states in the Upper Mississippi Valley—Illinois, Wisconsin, Minnesota, Iowa, Missouri, the Dakotas and portions of Nebraska and Kansas. In this same area also are marketed vast quantities of coal from West Virginia, Kentucky, Pennsylvania, and elsewhere, fuel oil from local refineries and from Mid-Continent plants, and natural gas from Kansas, Louisiana, and the Panhandle of Texas. This Upper Mississippi Valley is a battle ground for competing fuels from widely separated regional sources. Each fuel industry is equipped and prepared to supply a far greater quantity of fuel in its own normal market than the market requires.

NEED OF AN ANALYSIS OF ENERGY CONSUMPTION

Many producers of Illinois coal desire an analysis of the energy consumption in the Illinois coal market area, the extent and capacity of the energy market, the contribution made by each of the several energy sources, the past and present trends, and the competitive position of each fuel. Such an analysis is a necessary step to the formulation of an intelligent program of preparation of materials for the market and of marketing these materials. Unnecessary expenditures can be avoided and more effective practices can be undertaken. Such an analysis will also shed light on needed forms of cooperation among producers, on needed harmonious relations between employers and employees, on needed closer relations between producers and consumers of coal, on ways to improve marketing practice by retail dealers and finally, on the merits of proposed legislative measures with reference to public welfare.

DISTRIBUTION AND MARKETING PROBLEMS

Distribution and marketing will probably command the major attention of the industry in coming years. The most effective marketing methods require careful planning and thoroughly organized merchandising. Wastes will probably

be uncovered that are even larger than those which have been eliminated in production. Methods will be devised to break down distribution and selling costs and to effect more intelligent pricing. The relationships of consuming groups which have become altered will be disclosed and the areas in which the different products are supreme will be clearly recognized. Technical research will reinforce market research in improving the products for known needs, in finding needs for existing products, and in creating new products which will find new outlets. The successive step after production, namely distribution, calls for as systematic and thorough-going a regimen of research, analysis, and education as does production.

The coal industry is apparently no exception to the general law of industrial development in which three successive stages are noted. First is the phase of infancy in which the industry creeps, next comes the phase of expansion in which it runs, and third the phase of so-called stabilization or saturation in which it settles down to a steadier, more uniform pace until something new upsets the controlling factors.

Thus, instead of a straight line being representative of growth of demand for the long term, we have an "S" curve stretching across the chart of volumetric progress.

During the period from 1895 to 1918, when the coal industry stopped creeping and began to run, when the steep part of the "S" curve traced its upward course, there was little need for intensive scientific merchandising. Production was the keynote.

The close of the period of rapidly expanding markets, in 1918 and 1919, found the coal industry preparing for an ever increasing demand. The severe economic depression of 1921 was regarded as a temporary cessation in coal demand and not the beginning of a slow decline which became increasingly manifest in the intervening period from 1922 to 1929. During the severe depression from 1929 to 1934 the necessity for a study of markets and distribution problems came home to the industry.

The salvation of the coal industry lies in its having become distribution-minded. Distribution-mindedness gives rise to creative merchandising. And the extension of creative merchandising with its relatives of product research, market analysis, breakdown of sales costs, lowering of sales resistance by the determination of geographical supremacy areas, effective and intelligently selected and directed promotion, form perhaps the strongest counter force that the coal industry can set against narrowing margins of profit and decreasing volume of business.

BOUNDARIES OF THE ILLINOIS COAL MARKET AREA

The Illinois coal market area is defined as the territory included in the states of Illinois, Missouri, Iowa, Minnesota, and Wisconsin, the eastern cities of Kansas and Nebraska, and a small section of the Dakotas. The boundaries of this so defined "Illinois coal market area" are determined by competition from

other coal fields and other forms of fuel. Within the area so described 90 per cent of Illinois coal is marketed. In the southwest, fuel oil and natural gas dominate the market almost to the exclusion of coal. The westward movement of Illinois coal in Kansas, Nebraska, and the Dakotas is met by an eastward flow of coals from Colorado, Wyoming, and Montana. In the lake shore counties of Minnesota and Wisconsin, the market is dominated by Appalachian coals, cheaply carried over the Great Lakes and reaching the ports of Lake Michigan and the head of Lake Superior. Illinois coals, however, are marketed to a considerable extent in the southern and western sections of these two lake states. Only small quantities of Illinois coals are shipped east of the Illinois line. This market area is occupied almost entirely by the neighboring coal fields of Indiana and the Appalachian coal fields of Ohio, West Virginia, eastern Kentucky, and Pennsylvania.

With the above factors in mind, the map of the Illinois coal market area may be visualized. This constitutes the area which is logically and economically served by Illinois coal.

COMPETITIVE FUELS WITHIN THE ILLINOS COAL MARKET AREA

The Illinois coal market area, however, is by no means exclusively dependent upon coal from the Illinois mines. The preponderance of Appalachian coal in Wisconsin and Minnesota has been mentioned. Appalachian coal, also, moves in large tonnages into Illinois itself, particularly the Chicago district. In the States of Iowa and Missouri local coals share the market with coal imported from Illinois.

Throughout the market area, fuel oil and natural gas are also important factors in the total energy supply. Table 1 gives a summary of energy consumption in the Illinois coal market area in 1929, the year when a special distribution study was made by the U. S. Bureau of Mines. This includes coal consumption in Lake County, Indiana, as part of the Chicago fuel district.

TABLE 1.—SUMMARY OF ENERGY CONSUMPTION IN THE ILLINOIS COAL MARKET AREA IN 1929 [a]
(Exclusive of gasoline)

	Quantities	Tons or equivalent in tons of coal[b]
Coal, bituminous, tons		102,858,155
Coke, tons		4,580,764
Briquets, tons		687,377
Anthracite, tons		2,705,946
Fuel oil, barrels	28,871,165	6,880,000
Natural gas, M cubic feet	95,410,000	3,816,400
Water power, M K.W. hrs	2,814,435	2,378,000

[a] Compiled from Reports of U. S. Bureau of Mines and U. S. Geological Survey.
[b] The following ratios are used in converting fuel oil, natural gas, and water power into the equivalent of one ton of coal:
Fuel oil—4.2 bbls.
Natural gas—25,000 cu. ft.
Water power—1 kw. hr. = 1.69 pounds of coal.

MODERN CONDITIONS OF ENERGY PRODUCTION AND CONSUMPTION

Fuel resources and energy production are the bases of economic development, machine industry, transportation, and commerce in the present age. In the nineteenth century coal was the major source of energy generally available and played the leading rôle in industrial economy. In early decades of the twentieth century other sources of energy have become formidable competitors—fuel oil, gasoline, natural gas, and water power.

The history of energy utilization reveals a remarkable evolution in the relative importance and changing functions of these forms of energy. Before fuel technology attained such large significance, each of the energy groups occupied a position almost to the complete exclusion of the others. Anthracite was used principally in the field of domestic heating; bituminous coal dominated in transportation, manufacturing, and smelting; gas was used mainly for lighting and cooking; water power became associated with the infant but rapidly growing electric light and power industry.

These more or less sharply defined functions of the energy groups are tending to disappear. Fuel technology has widened the field of service for each of these energy sources so that all of them are competing more or less sharply with, and supplementing each other. The product of petroleum, e. g., fuel oil, encroaches upon the use of coal in domestic heating, water and rail transportation, gas making, central station fuel, and industrial heating. Coal, on the other hand, in a pulverized form, bids fair to assume the properties and perform the services of a liquid fuel. Water power experiences a rapid rise with the expansion of the electrical industry only to find its further expansion made difficult by the increasing efficiency and lower operating costs of the steam-electric plants.

The trend among fuels since 1900 has been marked by a rise in the relative position of fuel oil, water power, and natural gas in competition with coal. Prior to 1900 coal was the chief source of modern energy, and its consumption throughout the world was steadily increasing. Since 1913 the production of coal has increased but slowly, and a serious depression has developed in the older and more important centers of coal production. The depressed condition of the coal industry is due to a complicated series of new developments and not predominantly to any single cause.

The main causes of depression in the older coal mining regions, in spite of an increasing total consumption of world energy, are:

(a) The increase in the amount of useful energy secured from a ton of coal

(b) The competition of new coal fields

(c) The rapid expansion of the production and consumption of oil products

(d) The increasing surplus of natural gas

(e) The development of hydro-electric power

Increased output of energy from coal.—The greatest progress, in increasing the amount of useful energy secured from a ton of coal, has been the result of active research by large consumers of energy in an effort to reduce the cost of production of their services or products. Public utility companies, railroads, and producers of coke and iron and steel have been particularly active. The recovery of heat from waste gases, saving the gas from by-product coke ovens, improvements in boiler efficiency, extensive use of automatic feed and control devices, and better combustion obtained through the use of powdered coal are notable developments. The development and sale of electric power by large central plants, fuel or hydro, has been a tremendous factor in fuel economy. It has meant the elimination of a large number of small coal-burning power plants.

The average consumption of fuel of the public utility plants in the United States in 1934 was 1.45 pounds per kilowatt-hour as compared with 3.2 pounds in 1919. This alone resulted in a reduction of 40 million tons of coal requirements. It is estimated that the progress made in the past ten years in the more efficient production and use of energy for industrial purposes has meant a saving of probably at least twenty-five per cent in the fuel requirements for the delivery of the same amount of energy.

Competition of new coal fields.—Increased coal production from new fields has meant decreased output and depression in the older coal mining areas. Particularly notable has been the expansion of coal production in West Virginia, and in eastern and western Kentucky, which is reflected in a depression in the older fields of Pennsylvania, Ohio, and Illinois, and has resulted in capacity for over-production and increased competition of coal with coal.

Expansion in the use of oil products.—Fuel oils, including crude oil used direct, refinery gas oil, and fuel oil, represent the most direct competition with coal. Practically all the fuel oils are used in the production of heat and power and may be considered as filling a demand that would otherwise have been met primarily by coal. As more than sixty percent of the world output of fuel oil is consumed in the United States, it is evident that fuel oil is a factor in keeping coal production in this country at an almost stationary point.

A study of the distribution of fuel oil consumption in relation to coal production indicates that the chief use of fuel oil has developed in areas outside of the main coal producing zones, or near the points of oil refining. The present distribution of fuel oil consumption in the Illinois fuel area corresponds closely with the centers of refining. Illinois consumes approximately one-half of the total, mostly in the Chicago district. Adjacent areas, in Indiana, Wisconsin, and Michigan, use most of the remainder.

Relatively, however, fuel oil consumption in the Illinois fuel area has never been large. It now represents primarily the by-product of the local refining industries. The abundance of cheap coal has restricted fuel oil consumption to a limited number of uses in which it could find the best market. If progress in

the refining industry further tends to decrease the amount of fuel oil recovered from crude, the consumption in this region could readily adapt itself to decreasing supply. Use for domestic heating would probably be the most persistent in such an event, although the development of automatic stokers for coal-burning and the widening area of natural gas distribution may be important modifying factors.

Increasing supply of natural gas.—The consumption in the United States of 95 per cent of the world's supply of natural gas is an important factor in the competitive energy situation not found in other countries. While natural gas has long been a source of fuel in the Appalachian Field, its output there is declining, and the expansion in output in recent years has come from Louisiana, Texas, Kansas, and California. Natural gas must be distributed by pipe-line and, consequently, its competition with coal or fuel oil is limited by the radius of profitable distribution. The principal consuming areas have been in or near the oil and gas fields themselves and the largest uses have been for field operations, oil refinery fuel, and carbon black manufacture, while industrial and domestic heating consumed minor quantities. The construction of long distance pipe-lines from the Mid-Continent gas fields to Chicago, Indianapolis, and other cities of the interior states is an indication that large supplies of natural gas are available and that a new competitive factor has been added for both fuel oil and coal. The extension of the market for natural gas is so recent that it is still difficult to estimate its full effect.

Development of hydro-electric power.—The development of hydro-electric power, while showing a steady upward trend, is not important in the district served by Illinois coal. The water power installations in Wisconsin, Minnesota, Iowa, and Illinois, in their aggregate output do not exceed the equivalent of two million tons of coal annually. [1]

SUMMARY OF OBJECTIVES AND SCOPE OF THE PRESENT STUDY

The Illinois coal industry is vitally interested in this rapidly changing energy market described above. The coal fields of Illinois rank next to those of Pennsylvania and West Virginia in output, and are located in the tremendous energy-consuming market the center of which is the city of Chicago and the outer limits of which extend to the cities of eastern Kansas and Nebraska, and into the states of Missouri, Iowa, Minnesota, and Wisconsin. The market area is by no means occupied by products of the Illinois coal mines alone. It is a battle ground for the coal producers of the Appalachian and western Kentucky fields, for the fuel oil producers of the Mid-Continent fields and the natural gas of Oklahoma and Texas. The Illinois producers find their keenest competition in the Lake Dock territory from the lake-borne Appalachian coal. Crude oil and natural gas, carried by pipe line into the Chicago district, release competitive fuels in this important industrial center. The competitive struggle among the fuels has never

[1] Calculated on a basis of 1.55 lbs. of coal required to produce a kilowatt-hour of electric energy.

been as keen as it is today. The future of Illinois coal rests largely in its ability to meet this competition—both of outside coals and other types of fuel—in the energy market area served by Illinois coal.

The objective of this study is to make a detailed analysis of the nature and extent of the competition from other sources of energy with the view of evaluating the economic position and outlook for the Illinois coal industry. In order to obtain a proper perspective of the place that Illinois coal occupies in the total energy demand of the area under consideration, the scope of this study must include an analysis of the energy contribution of fuel oil, natural gas, coal from outside fields, and water power, as well as the quantity of coal supplied by Illinois itself. The contribution of each of these energy sources must necessarily be reduced to a common basis of comparison, e. g., the ton of coal as basic unit and the other energy sources stated in terms of equivalents of a ton of coal.

The survey will concern itself, not only with the existing competitive situation, but also with the trends of consumption of each of the fuels over a number of years. Changes in the competitive situation among the fuels may thus be traced and the probable future trends more critically analyzed.

An important factor in the competition among coal fields is the freight rate structure. The rates on coal are determined by the Interstate Commerce Commission and are beyond the jurisdiction of competing coal fields or competing coal-carrying railroads. The fate of mining fields or entire mining districts may hang upon the decision of the commission. A study of the freight rate structure is, therefore, an essential step in understanding the competitive relationships among coal producing fields or districts.

In addition to the competitive struggle among coal fields themselves, the rise of oil and gas competition, and the controlling influence of the Interstate Commerce Commission, the coal industry cannot fail to be cognizant of the increasing efficiency in coal utilization. The latter factor is as much responsible for the flattening curves of coal consumption since 1918 as the rising tide of substitutes.

A diagnosis of the factors which stimulated both the rise of substitute fuels and the increased economy of consumption is exceedingly difficult and complex, but, no doubt, the price factor has been an important contributor. In the prewar period, with the spot price of coal averaging $1.20 at the mine, the production of bituminous coal had consistently doubled each decade. This had become an accepted performance upon which coal-company expansion and financing programs were predicated. It was inconceivable to the coal man that there could be any break in this long-established precedent. Then came an era of high prices, resulting from the disturbances of the world war. Coal prices rose from an average level of $1.20 per ton to $2.60 per ton[2] in 1916, at the mine.

This extraordinary doubling in the price of coal, almost overnight, stands without a precedent in the century-old history of the coal industry. There can

2 Shurick, A. T., Coal prices can meet competition: Forbes, April 1930, p. 19.

be little question that this acted as a powerful incentive toward economizing in the use of fuel. With coal at $2.60 per ton, there was immediate justification for large capital expenditures in fuel-economy equipment.

The various changes in energy supply and utilization indicated in this brief summary are so far reaching and complicated in their effects and interrelations that they may well be termed revolutionary. It has been the primary purpose of this introductory chapter to present an outline picture of the whole problem and to indicate the position of coal in relation to the total energy market, before proceeding to a more detailed study of the trend of coal production and consumption.

CHAPTER II

COMPETITIVE POSITION OF SOLID FUELS IN THE ILLINOIS COAL MARKET AREA

TOTAL SOLID FUELS CONSUMED IN THE ILLINOIS COAL MARKET AREA IN 1929

The Illinois coal market area consumes solid fuels of various kinds obtained from several sources within and outside of its boundaries. The principal fuel is bituminous coal, but anthracite, coke, fuel briquets, and even wood contribute to its fuel needs. The principal sources of outside fuel are the coal fields of West Virginia, Kentucky, and Pennsylvania with smaller quantities imported from Ohio and Virginia.

The total quantity of solid fuels consumed within the area in 1929, for which year detailed distribution data are available, is shown in Table 2.

TABLE 2.—SUMMARY OF SOLID FUELS USED IN THE ILLINOIS COAL MARKET AREA IN 1929 [a]
(net tons)

Fuels	*Tons*
Bituminous coal	102,858,155
Coke	4,580,764
Anthracite	2,705,946
Briquets	687,377
Total	110,832,242

[a] Illinois, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas.

THE DISTRIBUTION OF BITUMINOUS COAL IN 1929

The distribution of coal from producing field to the ultimate market is least well known of all the elements of the coal trade. The first detailed report of distribution and consumption was issued for the year 1915 by C. E. Lesher, geologist in charge of coal statistics for the U. S. Geological Survey, and published in the annual report on mineral resources.[1] Two years later, a similar report was prepared for the United States Fuel Administration in connection with the proposed allotment of bituminous coal from producing districts to consuming states.[2] Since the close of the World War the competition between the bituminous coal-producing districts in the United States for the market is yearly increas-

1 U. S. Geological Survey, Mineral Resources of the United States, 1915, Pt. II, nonmetals, pp. 433-513.
2 U. S. Geological Survey, Mineral Resources of the United States, 1917, Pt. II, nonmetals, pp. 1203-1259.

ing in severity. The extent and nature of the demand is moreover of ever-present interest to the coal industry, because more than 95 per cent of the coal produced in the United States is used within the country.

The largest problem confronting the operator of a coal mine is, of course, that of markets, and whoever produces or sells the coal must consider in a broad way the possible markets not only as to quantity but as to quality. The cost of mining, the largest element of which in most shaft mining is the cost of labor, and the cost of transportation, regulated by the Federal Government through the Interstate Commerce Commission, impose definite limitations upon the markets that may profitably be reached by any coal. A study of the movement of coal from producing field to consuming state serves to outline clearly the general market territories for each major producing field or province. Since the surveys of 1915, 1917, and 1918 were made, significant changes in production and movement have occurred so that another survey of coal distribution was desirable. Eastern and western Kentucky had risen from small beginnings to places of prominence. The origin of coal consumed in the Lake Dock territory had undergone important shifts and new coal fields played an important part in supplying the large Chicago market. Accordingly a detailed survey was undertaken by the Coal and Coke division of the U. S. Bureau of Mines under the direction of Mr. F. G. Tryon for the year 1929.

This year was chosen for analysis as being more representative of normal conditions than the depression years that followed. Table 3 presents the data selected from the U. S. Bureau of Mines reports which are of interest to the coal producers of the Illinois field. The consuming states included in this table are Illinois, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas. These states represent a more or less well defined industrial and energy consuming unit. They also represent a battle ground for coal from competitive fields, east and west, and for other fuel and energy sources, mainly fuel oil and natural gas. Illinois coal, although meeting substantial competition from fuel and energy sources derived from outside of this geographic area, finds it principal outlet in these states. The principal competition from Appalachian coal fields is in Chicago and the western Lake Michigan shore as far north as Green Bay, Wisconsin, and the Duluth-Superior coal distibuting radius. With the exception of Chicago, the Illinois coals are practically excluded from these markets. On the west the movement of Illinois coal is practically limited to the eastern cities of the Dakotas, Nebraska, and Kansas. Local coal supplies, coal from Wyoming, Colorado and Arkansas, fuel oil, and natural gas also compete in this energy market.

A movement of Illinois coal down the river to the lower Mississippi Valley states has practically disappeared with the advent of fuel oil and natural gas.

ORIGIN OF COAL CONSUMED IN THE ILLINOIS COAL MARKET AREA

Table 3 shows the origin of coal consumed in this market area by principal groups of producing fields. In view of the fact that the energy market in Nebraska and Kansas is supplied to such a large extent by fuel oil and natural gas from the Mid-Continent field as well as coal from several states outside of Illinois, two totals have been included in the table, the first of which is exclusive of these two states. On the other hand the Dakotas have been included in the first total, even though their consumption of Illinois coal is relatively small, because in these states the energy market is largely supplied by coal while fuel oil and natural gas constitute a minor factor. An examination of these totals discloses the relative importance of the various Appalachian fields as well as the distribution of coal movements by all-rail haul and over the lakes. The concentration of lake coal in Illinois (mainly Chicago), Wisconsin, and Minnesota is apparent. The advantage of low cost transportation into this part of the market is so pronounced that Illinois coal producers will find difficulty in overcoming the handicap of all-rail haul from the southern part of the State.

The wide distribution of all-rail coal from the Appalachian fields into the Illinois coal market area, however, is made in the face of higher transportation costs. This is particularly true of the New River-Winding Gulf and Pocahontas-Tug River in the low volatile fields of West Virginia, and the Kanawha, Logan, Kenova-Thacker, McRoberts, and Harlan-Benham fields in the high-volatile districts of West Virginia and eastern Kentucky. Transportation rates from these fields to Chicago vary from $3.09 to $3.29 per ton with correspondingly higher rates to points in the Illinois coal market area farther into the interior. Yet in 1929, the fields mentioned above shipped by rail 23,788,511 tons into this market area. The distribution of so large a quantity of coal is accomplished therefore upon factors other than transportation advantage. Some of this is due to demand for coal of special quality, as for example coking coals, or smokeless coals. Some of the coals find a preferential market among domestic consumers, public utilities, and railroads. Lower wages in the southern Appalachian field has been a factor in permitting an outlet for these coals in the Middle West. These factors are not of such a nature, however, that they cannot be overcome and a part of this market again returned to the coal fields of southern Illinois.

West of the Mississippi River, the Illinois coal producers find, in addition to sharing the market with the Appalachian coals, a considerable competition from local coal fields in Iowa, Missouri, and Kansas, and a smaller, though active, competition from southwestern and Rocky Mountain coal fields.

[a] Compiled from Supplements 1, 3, 4, and 6 of the Monthly Coal Distribution Reports, August, October, November, 1931, and January, 1932, U. S. Bureau of Mines.
[b] Includes some coal shipped to the Chicago district lying in Indiana.

COAL LOCALLY USED

In addition to the coal which is shipped to consuming states by rail or lake, the coal producing states within the Illinois coal market area dispose of small quantities in coal mining localities which do not enter railway shipments, and use some in colliery operations. The total so used in 1929, as shown in Table 3, was 7,144,695 tons.

RAILWAY FUEL

In compiling statistics of coal distribution, it is necessary to show the large item of railway fuel separately as the consumption of carriers cannot be identified with a particular state. Hence the consumption of railway fuel, 27,778,390 tons, in 1929 requires interpretation. Of this total, 4,219,661 tons delivered at docks on Lakes Michigan and Superior, presumably was used mostly in the states comprising the Illinois coal market area. It is doubtful if any but a negligible quantity was carried beyond the limits of this market territory. All of this coal was, of course, received from the Appalachian fields. Distribution of Illinois coal among the railroad regions was quite widespread as shown in Table 4.

TABLE 4.—DISTRIBUTION OF ILLINOIS COAL FOR RAILROAD FUEL IN 1929 [a]

Region	Illinois	Iowa	Kansas and Missouri	North Dakota
New England

Southwestern region	2,025,903		1,364,385	
Total	19,910,681	1,563,547	1,858,327	28,911

[a] Distribution of Coal Shipments: U. S. Bureau of Mines, Monthly Coal Distribution Report No. 8, March, 1932, p. 7.

The railroads are normally one of the largest coal consuming groups and, as such, the trend of railway coal consumption is of vital interest to the producers. Changes that have occurred in the consumption of railway fuel are analyzed for the country as a whole in Chapter VIII.

Since the competitive position of the various coal fields lying within and without the Illinois coal market area is the resultant of the combined factors of mine price of coal, transportation costs, quality of coal, and type of consumer, a further detailed analysis of the market position of lake cargo coal, all-rail haul from the Appalachian fields and coal fields adjacent to the Illinois districts (i. e., Western Kentucky, Indiana, Iowa, Missouri, etc.) will be made separately. Before undertaking this analysis, however, a brief discussion of coke, anthracite, and briquets will be undertaken.

DISTRIBUTION OF COKE AND BRIQUETS IN 1929

The growing market for domestic by-product coke is the outstanding feature shown by the analysis of coke distribution in 1929. Ten years previous the consumption of coke for domestic purposes in the entire nation was equal to that consumed in the Illinois coal market area in 1929. Importation of coke from outside states makes up about half of the total. Presumably the major portion of this represents coke shipped from the coke ovens in Northern Indiana, although substantial quantities are also received from Alabama, Michigan, Ohio, and Pennsylvania.

Two-thirds of the fuel briquets produced in the United States are consumed in the Illinois coal market area. Nine of the twenty-four briquetting plants in operation in the United States in 1929 to 1933 are located in the Illinois coal market area. The location of the plants, the date put in operation, and the raw fuel used is given in Table 5.

Table 5.—Briquetting Plants in the Illinois Coal Market Area

Location		Date put in operation	Raw fuel used, as reported by the purchaser
State	City		
Minnesota	Duluth	1933	Anthracite and bituminous slack
Missouri	Kansas City	1909	Semi-anthracite
Nebraska	Omaha	1932	Petroleum coke
North Dakota	Lehigh	1929	Lignite char
Wisconsin	Superior	1912	Bituminous slack
Wisconsin	Ashland	1931	Bituminous slack
Wisconsin	Superior	1909	Anthracite and bituminous slack
Wisconsin	Milwaukee	1928	Bituminous slack
Wisconsin	Sheboygan	1933	Bituminous slack

The briquetting industry in these states is built mainly upon the utilization of waste or by-products of the coal trade. Trans-shipment of coal over the lakes to upper lake ports results in the accumulation of slack coal and fines which would have no market otherwise. In the case of the North Dakota plant the operation is obviously based upon an attempt to improve local coals. An attempt to find a satisfactory domestic fuel to replace the high priced Pennsylvania anthracite is an important element in supporting a briquet industry in these states.

ANTHRACITE SHIPMENTS INTO THE ILLINOIS COAL MARKET AREA

Pennsylvania anthracite has been an important factor in the domestic market of the Lake Dock territory of the Illinois coal market area, but its significance appears to be declining. Shipments over the lakes since 1921 are given in Table 6.

TABLE 6.—ANTHRACITE SHIPMENTS INTO THE ILLINOIS COAL MARKET AREA [a]

1932[b]	294,000	66,000
1933[b]	426,000	135,000

[a] Tryon, F. G., Mann, L., and Rogers, H. O., Coal in 1930: U. S. Bureau of Mines, Mineral Resources of the United States, 1930. p. 727, 728.
[b] Minerals Yearbook, 1932-33, p. 439; 1934, p. 563.

A small quantity of anthracite included in the first column reaches Canadian ports but the item is so small as to be practically negligible. For example, in 1928, Fort William, Ontario, received 46,000 tons, and Sault Ste. Marie, 5,000 tons.

All rail shipments of anthracite from the Pennsylvania fields to the Illinois territory amounted to about 1.3 millions tons in 1929.

SUMMARY OF 1929 FUEL DISTRIBUTION

Tables 2 and 3 give a detailed picture of the movement and distribution of solid fuels in the Illinois coal market area for 1929. It should be noted that the figure of coke consumption is not altogether an additional quantity of fuel but represents, in part, a conversion into coke of coal shipped into the territory and included in Table 2. Since 1929 local changes in consumption of fuels has no doubt taken place. The broad picture, however, remains unchanged.

COAL CONSUMPTION IN THE ILLINOIS COAL MARKET AREA IN THE PERIOD 1930-1934

Since the compilation of the coal distribution data for 1929, data have been made available for the movement of coal from principal producing fields to states and important urban market centers in the Illinois coal market area. Data for coal shipments are shown in Table 7. This table shows the movement of revenue coal (exclusive of non-revenue railway fuel) from producing field to consuming state or city.

The movement of coal for the year 1932 from Illinois and competing eastern fields is shown on Plates I, II, and III (pocket). Plate I shows the shipments of coal from Illinois into the states comprising the Illinois coal market area. The influence of lake cargo coal competition is shown by the small shipments of Illinois

coal into Wisconsin, and similarly, the influence of fuel oil and natural gas is shown in the low consumption of coal in Kansas.

Plate II shows the origin and destination of railway shipments from Indiana, western Kentucky, and from the Appalachian coal fields into the Illinois coal market area. The most important contributors are the Kanawha, Logan, Kenova-Thacker, New River-Winding Gulf, and Pocahontas-Tug River fields in southern West Virginia, and the fields of Indiana and western Kentucky.

Plate III shows the origin and destination of lake cargo coal from the Appalachian fields into the Illinois coal market area. The southern Appalachian coal fields in eastern Kentucky and West Virginia are the principal contributors to the lake trade.

In addition to all-rail shipments into the Illinois coal market area, a substantial quantity of coal is received over the Lakes by ports on Lake Michigan and Lake Superior. Shipments to American ports on these lakes in from 1929 to 1934 are given in Table 8.

[a] Monthly Coal Distribution Reports, U. S. Bureau of Mines.
[b] Not available.

Although the quantities of coal distributed and consumed in this area vary from year to year and have declined substantially since 1929, the underlying conditions bringing about the distribution characteristics of 1929 have not changed appreciably.

ECONOMIC FACTORS UNDERLYING THE DISTRIBUTION OF COAL IN THE ILLINOIS COAL MARKET AREA

Several distinct coal movements must be considered in describing and analyzing the competitive position of outstanding fuels into the Illinois coal market area. The principal ones are:

(1) The rail-lake haul to the Upper Lake Dock territory.
(2) The all-rail haul from the several Appalachian coal fields in Pennsylvania, northern West Virginia, southern West Virginia, and eastern Kentucky to Chicago and other Mid-Western points.
(3) The western Kentucky movement into the southern portions of the Illinois coal market area.
(4) The eastward shipments from Rocky Mountain coal fields.

[c] Less than 500 tons.

The Lake cargo movement.—Appalachian coal moves into the mid-western and upper Lake states—principally Illinois, Wisconsin, Minnesota, and the Dakotas—in competition with coal from the producing fields of Illinois, Indiana, and western Kentucky. The apparent anomaly of a distant coal field entering a market already equipped with a local coal supply and coal-mining industry is the outcome of several factors, among which are:

1. Low water transportation rates.
2. Coal suitable for coking or other special purposes.
3. Difference in wage levels between eastern and western fields.
4. Summer work to supply the lake trade while the local demand is at a low ebb.

[a] Supplement to U. S. Bureau of Mines Coal Distribution Report No. 3, October 20, 1931, p. 14.
[b] Included in Illinois, other.

Table 10 gives a detailed statement of the distribution of coal moved over the Great Lakes in 1917 and 1929, including that used for railroad fuel, bunker coal, exports to Canada, and shipments to states not in the group included in the Illinois coal market area. This table discloses certain shifts in the market. The market outlet for lake cargo coal has decreased generally in the inland states but has shown substantial increases in those states bordering the lakes. Especially notable has been the growth in Illinois and Indiana where consumption has increased from 1,613,171 tons in 1917 to 5,367,913 tons in 1929. Of this quantity 5,100,122 tons of lake cargo coal was consumed in Chicago in the latter year.

In Table 9 is given comparative data on the shipments of coal from the Eastern Interior coal field and the lake cargo coal into the states bordering the lakes. Tonnages reported for the Eastern Interior coal field represent about 90 per cent of the coal moved from these states into the lake states.[3] This table shows the extent to which Illinois coal shares the lake states market with the associated coal fields of Indiana and western Kentucky as well as with the Appalachian fields.

[3] Data supplied by Mr. Jonas Waffle of the Coal Trade Association of Indiana.

The generally downward trend of coal shipments from Illinois and Indiana is offset by increases from western Kentucky. Nevertheless, the combined shipments from the three states comprising the Eastern Interior coal field is declining while shipments over the lakes are increasing.

Economic basis of the Lake cargo traffic.—The large market outlet for Appalachian coal in the lake states rests upon a lake-rail transportation combination which permits a lower delivery cost than the all-rail haul from the southern Illinois fields. Difference in the value of coal at the mines, differences in the quality of coal, and control of marketing agencies are contributing causes but the dominant factor is the freight rate structure. In delivering lake cargo coal to the states of Wisconsin, Minnesota, and the Dakotas, three major items enter into the cost of transportation. These are: the railroad rate from the coal fields to the lower lake ports; the lake haul; the railroad rate from upper lake ports to interior points. This complex transportation system affects three groups of competitors, namely, the northern Appalachian fields, mainly Pennsylvania, Ohio, and northern West Virginia; the southern Appalachian fields, mainly southern West Virginia and eastern Kentucky; and the Eastern Interior coal fields of which the Illinois fields are the leading ones.

The competitive position of the northern and southern Appalachian fields is affected by the first component of the transportation system, i. e., the rail rate from the fields to lower lake ports. The long and bitter struggle between these two groups of coal fields is not pertinent to the present discussion except to point out that the southern fields have gradually gained the ascendancy in supplying the lake cargo trade.

The factor of crucial interest is the position of Illinois in competition with lake cargo coal and this revolves around the element of delivered costs. Since lake rates are so exceedingly low per ton mile in comparison with rail-rates, the lake cargo coal has an undisputed advantage in the upper lake ports on Michigan and Superior—Chicago, Milwaukee, Kenosha, Sheboygan, Manitowoc, and Duluth-Superior. When, however, the lake cargo coal is re-shipped by rail to interior points in Minnesota and Wisconsin, freight rates add rapidly to the cost and a point is reached where the freight rates from Appalachian fields approach the all-rail rates from the fields of southern Illinois. The relation of transportation costs upon the competitive position of the lake cargo coal and the Illinois fields is shown in Table 11.

[b] Rates from Duluth to interior points.

The dominance of lake cargo coal in the area served by Duluth is explainable when comparative freight rates are examined. Only in the Twin Cities is the Illinois freight rate comparable with some of the more remote districts of the Appalachian coal field. The coal of northern Illinois, although of lower quality than either the southern Illinois coal or that from the Appalachian fields reaches the Twin Cities in rather large quantities. One very large consumer of coal who uses it exclusively in power production consumes well over 100,000 tons annually. It is well adapted to use in plants where boilers are equipped with travelling grates.[4]

Lake dock vs. all-rail coal.—While lake dock coal dominates the market in the Duluth area and is important in the Milwaukee distribution zone, there is still a substantial amount of all-rail coal coming into the market both from Illinois and from eastern fields. Several important factors determine which the coal dealer will purchase. Although price is the dominant factor, quality also plays an important part. All-rail coal is generally superior in quality, whereas dock coal is cheaper. The ability of all-rail coal to enter this market in spite of higher transportation costs is accounted for, in part, by the factor of degradation of lake cargo coal. This varies with the type of coal handled.

In its course from mine to consumer, coal passes through many handlings, most of them rough ones. When screened at the tipple it leaves the mine properly sized. All-rail coal before it reaches its destination encounters numerous bumps and other rough treatment with the result that there is much breakage.

"Coal subjected to dock handling suffers much rougher treatment than any rail-shipped car, and there is a corresponding increase in degradation. Upon leaving the mines it is taken to Lake Erie ports, where the cars are lifted and turned upside down and their contents poured into the holds of vessels. This fall of from twenty to fifty feet results in tremendous breakage. Upon arrival at the Superior dock, the boat is unloaded by means of six- or eight-ton clams, which crunch into the cargo and bite out clamfuls of coal, smashing much of it in the process. This is conveyed over a bridge to the dumping ground, where the clams open and spill the contents in another fall of from twenty to forty feet. When prepared to load, the clams again dig the coal out of these piles and drop it into the screening device, which separates it into sizes.

"The process results in a degradation at the docks varying from 5-6 per cent on the best grades of anthracite coal, which is more carefully handled, to 60 or 70 per cent on the brittle Pocahontas. This coal, when delivered to the retailer dealer, must be screened again if it is sold to domestic trade. The docks use a 1¼-inch screen for most of their rescreening and the dealer usually uses about the same measure. Everything that goes through the screen is sold as screenings."[5]

The above rather detailed description of the effects of handling upon the size of coal has been introduced because of its relations to one market group—the domestic user. Screenings are sold to industrial consumers frequently at prices below the delivered cost at the Upper Lake Docks. To insure an overall profit

5 Vaile, R. S., and Pickett, V. G., Coal Distribution in the Twin Cities, University of Minnesota Press, 1932, pp. 38, 39.

to the coal dealer, the retail consumer is called upon to pay a price for his coal that helps to offset the low price at which screenings are sold to the steam trade.

Lake trade and the Chicago coal market.—The Chicago coal market is of particular interest because of the large quantities of coal consumed, the several sources from which coal is obtained, and the diversity of the market. Table 12 gives a detailed statement of the quantities of coal shipped to the Chicago district in 1929 and the sources of the coal.

[a] U. S. Bureau of Mines, Supplement to Monthly Coal Distribution Report, Nos. 1-4, 6.

The wide diversity of sources from which Chicago obtains its coal supplies is a consequence of the nature of the market, quality of the coal, differences in the freight rate structure, and differences in the cost of coal at the mines.

Coking coal market.—One of the important outlets for coal in the Chicago area is the by-product coke oven. This includes the ovens in Gary and Iniana Harbor as well as those in the Illinois portion of the Chicago area. This district includes approximately 85 per cent of the oven capacity of Illinois and Indiana. The source and quantity of coal used in the ovens of these states in 1929 to 1932 inclusive is shown in Table 13.

[a] Authority: Interstate Commerce Commission.

The importation of from 10 to 14 million tons of coal from Appalachian fields into the Chicago market arises out of the need for coals suitable for the coking process and is not to be regarded as a competitive relationship between eastern and interior coal fields. The small quantity of Illinois coal entering this market is used mainly for mixing with eastern coals.

Apart from the coking coal industry, the Chicago market consumes coal for steam purposes, domestic heating, railroads, and in the "heat" industries, e. g., glass and clay products manufacture, etc. In these industries and markets the need for a special type of coal is not so exacting as in the case of coking coal. Competition among coal fields, therefore, becomes more a matter of cost, and cost is contingent upon freight rates and mine price. The comparative freight rate costs on coal from the fields supplying the Chicago market is shown in Table 14.

Although freight rates to Chicago from the eastern fields are lower over the lakes than by all-rail haul, the latter is apparently the favored method of shipment to the Chicago district.

Effect of West Kentucky development upon the Illinois coal industry.—The rise of western Kentucky coal production in competition with the older fields of Illinois and Indiana parallels the development of the southern Appalachian fields in West Virginia and eastern Kentucky at the expense of Pennsylvania and Ohio. While the rate of increase in western Kentucky has not been as phenomenal as in the eastern fields of that state, most of the increase has been shipped to states comprising the Illinois coal market area. A comparison for 1917, 1918, and 1929, three years for which detailed distribution data are available, shows the marked increase in the use of western Kentucky coal in Illinois and neighboring states. (Table 15).

[b] Not available.

Rise in shipments to Illinois, Iowa, Minnesota, Missouri, Nebraska, and Wisconsin has been particularly significant.

Competition of Western Interior and Rocky Mountain coal fields. —Illinois shares the market west of Mississippi River with the local coal fields of Iowa, Missouri, and Kansas, with coal imported from Arkansas and the Rocky Mountains, and with minor shipments from the Appalachian fields. The origin of coal consumed in the states comprising the Illinois coal market area is shown in Table 16.

In the coal producing states west of the Mississippi River particular attention should be called to the wide distribution of Arkansas coal. This product is of anthracite rank and is widely used as a domestic fuel. Competition with Illinois coal is most severely felt in Missouri. The coal fields of Iowa mainly serve a local market since more than 90 per cent of the total production (exclusive of railroad fuel) is consumed within the state. The local character of the coal industry in Kansas and Missouri is also evident from the restricted nature of the market. Eighty-three per cent of the output (exclusive of railway fuel) is used in Missouri and Kansas and more than 99 per cent in these states and Nebraska.

The competitive influence of Rocky Mountain coals is confined mainly to the western portions of this coal consuming area. Colorado coal is significant only in Kansas and Nebraska, Montana coal is confined practically to the North Dakota market, and Wyoming coal is important only in Nebraska and the Dakotas. Oklahoma, although considered outside of the Illinois coal market area, finds a considerable outlet in its neighboring states of Missouri and Kansas.

CHAPTER III

FUEL OIL IN THE ILLINOIS COAL MARKET AREA

IMPORTANCE AS A SOURCE OF HEAT AND POWER

The importance of fuel oil as a source of heat and power and a competitor of coal in the energy market is evident, not only from the large and diverse market for this fuel but also the consistent growth in consumption during the period for which records are available. The principal areas of fuel oil consumption in the United States have been in districts devoid of coal supplies such as the West Coast states, the North Atlantic Coast regions (including fuel oil used for bunkering), the Mid-Continent and Gulf Coast region, and the Chicago area. By comparison, fuel oil consumption in the Illinois coal market area has been a less important factor than the industrial eastern seaboard, or the crude oil producing regions in the Mid-Continent, the Gulf Coast, and California. The position of this energy market area as a consumer of fuel oil compared with the United States as a whole is as follows:[1]

	Consumption in 1934	
	Fuel oil (barrels)	Coal equivalent
United States	330,321,000	78,648,000
Illinois coal market area	33,302,000	7,929,000
Exclusive of Kansas and Nebraska	25,457,000	6,061,000

1 A. T. Coumbe, Jr., National distribution of fuel oil, 1931: U. S. Bureau of Mines. Mineral Market Report No. 415, Nov. 19, 1935.

Total consumption of fuel oil in the states comprising the Illinois coal market area and consumption by principal types of customers is given in Tables 17 and 18 below and figures 1 and 2. Total consumption in the area, as given in Table 17, is distributed among nineteen different consumer groups as listed in the annual reports on fuel oil distribution prepared by the U. S. Bureau of Mines.[2] In Table 18, consumption by six of the leading consumers groups which account for about 80 per cent of the total consumption is reported. Consumption of the re-

2 See "National Survey of Fuel Oil Distribution" for the years 1927 to 1931 by E. B. Swanson and others of the U. S. Bureau of Mines. The groups of consumers listed in these reports are railroads, steamships (including tankers), gas and electric power plants, smelters and mines, iron and steel products, chemicals and allied industries, automotive industries, textiles and their products, paper and wood pulp, logging and lumbering, cement and lime plants, ceramic industries, food industries, other manufacturing, commercial heating, domestic heating, U. S. Navy, Army transports, etc., fuel used by oil companies, miscellaneous uses.

[b] No data.

maining 20 per cent is among 13 groups of consumers each of which is so small as to have little effect upon the trend of fuel oil consumption. Of the six consumer groups which are separately reported in Table 18, the outstanding characteristic is the rapid increase in the use of fuel oil for commercial and domestic heating. In the remaining four groups consumption is either stationary or tending to decline. The factors responsible for the trends in each of these groups is a resultant of comparative price levels with coal, the factor of convenience, and the adaptability of a fuel in liquid form for certain specific purposes. Each of these will be analyzed in more detail in the discussion of the fuel consumption by industrial groups. The coal equivalent of fuel oil in the Illinois coal market area (exclusive of Kansas and Nebraska) is slightly in excess of 5,000,000 tons.

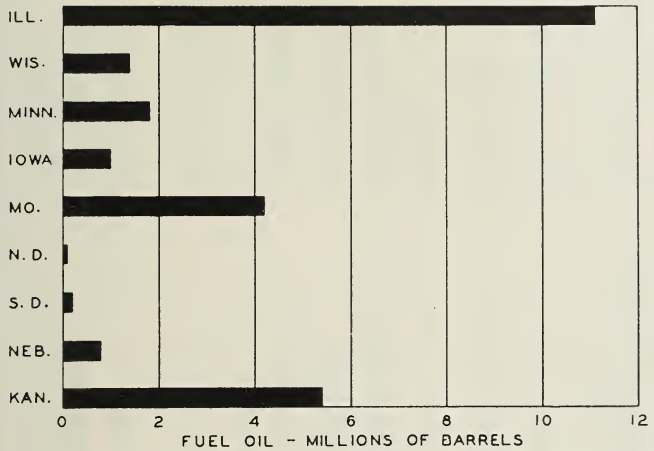

Fig. 1.—Consumption of Fuel Oil by States in the Illinois Coal Market Area.

COMPETITIVE POSITION OF FUEL OIL IN THE ENERGY MARKET

Conditions governing supply of fuel oil.—In order to evaluate the competitive position of fuel oil in the energy market, it is necessary that the economic nature of this product be clearly understood. Fuel oil is a by-product of the gasoline manufacturing industry. As a fuel it serves no peculiar need (with minor exceptions) that cannot also be supplied by coal. The large supply of fuel oil available in the United States is due to two factors: First, the nature of oil and the methods of refining were such as to yield a larger percentage of the by-product fuel oil than the cash crop of the refining industry—gasoline. Until 1925, 50 per cent or more of the products of crude oil was in the form of fuel oil; secondly, the mounting demand for gasoline occasioned by the rapid expansion of automobile output was accompanied by the production of correspondingly large quantities of fuel oil. In 1931 the domestic deliveries of fuel oil mounted to

313,092,780 barrels,[3] an equivalent of 74,545,900 tons of coal. Although the wider use of cracking methods is effecting a higher percentage of gasoline recovery, this has not brought about an appreciable decline in the available fuel oil supply. The key to the quantity of fuel oil supply is the rate of crude oil production. As long as crude is being produced in abundant quantities the refining end of the oil industry finds it more expedient to recover from the crude only the

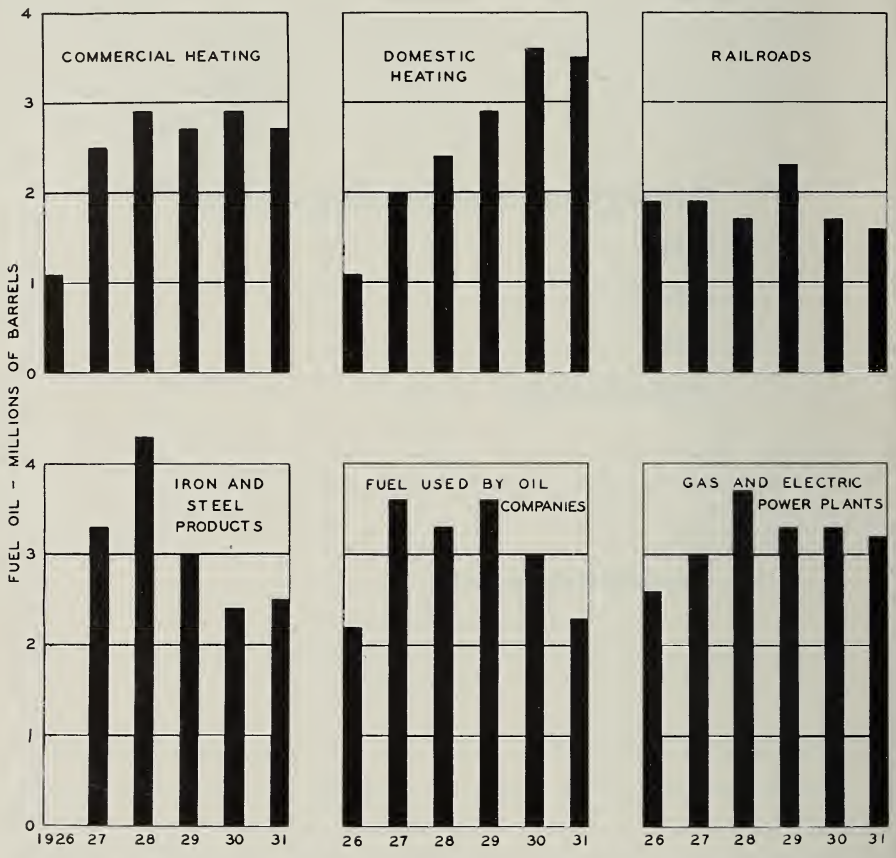

Fig. 2.—Consumption of Fuel Oil by Principal Uses in the States Comprising the Illinois Coal Market Area.

percentage of gasoline that can be obtained by skimming and cracking methods and throw the residue on the market as fuel oil at whatever price it will bring. A decline in fuel oil supply can be brought about only by controlling crude output to such a degree that rising prices of both crude and gasoline will reach a point where it is more profitable to increase the percentage of gasoline output by cracking and hydrogenation than it is to sell it as fuel oil. The oil industry is just

[3] U. S. Bureau of Mines, Fuel Oil Distribution in 1931.

emerging from a period of excessive production occasioned by discoveries of prolific producing fields and, unless further upsets occur, will be in a fair position to bring crude production more nearly in line with demand. This objective, if achieved, will result in a higher price for crude and gasoline, and eventually affect the price of fuel oil.

Conditions governing the distribution of fuel oil.—Since fuel oil is difficult to transport by pipe line and costly to carry by tank car, the key factor in determining the major areas of consumption is refinery location. In the Illinois coal market areas four well defined refinery centers may be discerned. These are

(1) The Chicago district.
(2) East St. Louis district.
(3) Eastern Illinois district.
(4) Kansas City.

Refinery capacities in each of the districts is given in Table 19 below:

TABLE 19.—APPROXIMATE DAILY CRUDE REFINING CAPACITY IN THE ILLINOIS COAL MARKET AREA

	Daily Crude Capacity Barrels of 42 gallons each
Chicago District	200,000
East St. Louis District	86,000
Eastern Illinois	26,000
Sugar Creek (Kansas City)	20,000
Total	332,000

The distance over which fuel oil can be transported from the refinery center to the consuming market is determind largly by the rate at which the freight charges bring the cost of fuel oil up to a competitive level with that of coal. Secondary factors which may enlarge somewhat the radius over which fuel oil is moved is a demand occasioned by special uses or convenience. The concentration of fuel oil utilization near the refinery centers is illustrated by data for consumption of fuel oil in manufacturing by counties as revealed by the Census for 1929. In that year the total consumption of fuel oil in the Illinois coal market area was as follows:

Entire Area ..... 28,871,165 barrels
Exclusive of Nebraska and Kansas ..... 22,343,644 barrels

Of this amount, the Census on "Consumption of Fuel and Electric Energy in Manufacturing Industries" allots to manufacturing the following amounts:

Entire area ..... 20,353,200 barrels (70%)
Exclusive of Nebraska and Kansas ..... 16,758,188 barrels (75%)

The degree to which this consumption is concentrated near the source of production is revealed in the map of consumption of fuel oil for manufacturing purposes by counties. Of the total fuel oil used for manufacturing in this area, the distribution is given in Table 20.

TABLE 20.—DISTRIBUTION OF FUEL OIL USED IN MANUFACTURING

Refining center	Near refining centers Consuming counties in	Barrels (42 gallons each)
Chicago	Wisconsin	1,572,530
	Illinois	5,611,815
	Indiana	6,083,004
Total		13,267,349
East St. Louis	Illinois	3,536,634
	Missouri	930,000
Total		4,466,634
Eastern Illinois	Crawford Co. }	685,650
	Lawrence Co. }	
Kansas City, St. Joseph	Missouri	1,091,572
Total		19,511,205

Next in importance to the refinery centers as consumers of fuel oil are the urbanized areas within these states. Consumption in the principal localities is as follows:

TABLE 21.—CONSUMPTION OF FUEL OIL IN URBAN AREAS

Area or city	State	Barrels (42 gallons each)
Tri-city district	Illinois	274,423
	Iowa	159,552
	Total	433,975
Peoria	Illinois	519,190
Danville-Champaign	Illinois	76,822
Joplin district	Missouri	23,262
St. Paul-Minneapolis area	Minnesota	596,482
Adrian Co.	Missouri	95,108
Henry Co.		88,988
Duluth, St. Louis Co.	Minnesota	58,925
Crown Wing Co	Minnesota	26,428
Total		2,023,787

Fuel oil consumed for manufacturing in the remaining counties of these states, after deducting the quantities used near the refining centers and the somewhat smaller quantities consumed in urban centers not located near refineries, amounts to 1,306,200 barrels (in the area exclusive of Kansas and Nebraska) or 7.8 per cent of the total used in manufacturing. While this distribution accounts for only that part of fuel oil consumption used in manufacturing, and does

not include fuel oil used for domestic and commercial heating and for railroads, nevertheless it represents 75 per cent of the total consumption and is a fair indicator of the geographical distribution of this type of fuel.

The above analysis implies that fuel oil is consumed near the source of production but takes no account of the balance between production and consumption within major refining zones. The situation in the Illinois coal market area is presented in Table 22 which gives production and consumption of fuel in the states comprising the Illinois coal market proper, and the same data for those states southeast of the Illinois coal market area in the Mid-Continent field whose principl refining area centers around Tulsa, Oklahoma. Indiana is included with the first group because of its large refining capacity near Chicago and a consequent outlet of its fuel oil into the Chicago area. The excess of production over consumption necessitates importation from the Mid-Continent field where the opposite condition exists. The transportation of fuel oil over this long distance was no doubt made economically feasible by the low prices prevailing in 1929, (Table 22) aided to some extent by cheap barge transportation over part of the distance.

TABLE 22.—CONSUMPTION AND PRODUCTION OF FUEL OIL, 1929 [a]
(In barrels of 42 gallons each)

[c] Included with Indiana.

Table 22 brings out clearly the fact that competition in the energy market from fuel oil is of more than local significance. The economic nature of this fuel as a by-product of the gasoline manufacturing industry and a fuel market of such a nature that an exclusive outlet does not exist compel the refiners to sell it at prices determined by the price of coal. An excess of the fuel over normal needs, both in Chicago and the Mid-Continent has the effect of further depress-

ing prices below the level of an equivalent quantity of coal with the consequence that long distance shipments become feasible. An uncontrolled output of crude oil, encouraging a surplus of gasoline manufacture, further adds to supply of fuel oil and makes the competitive battle more keen. This situation was sharply in evidence in 1931 when fuel oil prices at the Olkahoma refineries fell to 27½ cents per barrel. Until the key to the situation is removed, i. e., until the output of crude is controlled and the price is raised to a point where increased cracking and recovery of gasoline becomes profitable, the fuel oil factor will be of critical competitive importance in the energy market.

CONDITIONS GOVERNING THE FUTURE TREND OF FUEL OIL CONSUMPTION IN THE ILLINOIS COAL MARKET AREA

The extent to which fuel oil will continue to compete in the fuel market of the Upper Mississippi Valley states is dependent upon two variables:

(1) The rate at which crude oil is produced and run to stills.

(2) The rate at which gasoline is consumed.

The relationship between these two variables is the dominant factor in determining the price of crude oil, of gasoline and of the by-product fuel oil.

When crude is produced in abundant quantities there is a tendency for the refiners to increase runs to still and increase stocks of gasoline. An ensuing drop in gasoline prices forces the adoption of refining methods which result in the gasoline recovery of only that part of the crude which can be obtained by low-cost methods, e. g., skimming or topping. The improved practices which make possible a higher gasoline recovery by re-running and cracking are not utilized because they add to the cost and cannot be used by one refinery when others, by using large supplies of crude and straight-run methods of refining, are underbidding in the gasoline market. The entire procedure is accompanied by a large output of by-product fuel oil which in turn is thrown upon the market for whatever price it will bring. The significance of the procedure was concealed somewhat as long as the annual demand for gasoline was showing substantial increases, but with the turn of economic events in 1930, when increasing demand disappeared and the years immediately following showed slight decreases, the consequences of this uneconomic procedure became acute. Heroic measures on the part of the leaders among the oil producers, accompanied by ruthless and drastic measures on the part of state authorities in 1931, served to stem the flood of crude oil to the extent that production and consumption were more nearly balanced. Curtailed consumption of fuel, including fuel oil, in the business recession of 1930-31-32, however, more than offset the decline in crude oil production so that the situation still remains acute. Although fuel oil consumption actually declined in 1930-32 from the 1929 level, this decline was not as pronounced as that occurring in coal. Meanwhile the low prices quoted for fuel oil, 30 cents a barrel in the Tulsa area, in June 1932, indicates an abundant supply available to fuel users. The situation in regard to the surplus fuel oil available in the Tulsa refining area

is intensified by the rapid expansion of the natural gas industry of the Mid-Continent area and the ensuing displacement of fuel oil in many of the local industries.

The remedy for this unsatisfactory and uneconomic condition, to the producers of petroleum themselves, as well as to the competing coal interests, lies in a substantial reduction of crude oil output. This has been emphasized again and again by Federal and State authorities, by the leaders in the oil industry, and by the producers of coal. The economic basis of controlled production is tersely stated by President Coolidge in his letter of December 19, 1924, creating the Federal Oil Conservation Board. He says in part:

"Overproduction in itself encourages cheapness, which in turn leads to wastefulness and disregard of essential values. Oil, of which our resources are limited, is largely taking the place of coal, the supply of which seems to be unlimited, but coal cannot take the place of oil in most of its higher uses, on land or sea or in the air."[1]

In its first report the Federal Oil Conservation Board amplified the position of the President in a statement as follows:

"The most essential products from our crude oil are lubricating oil, gasoline and other oils for internal combustion engines. The other uses for oil could be dispensed with, without an industrial revolution, as other fuels and substitutes could be applied without prohibition differentials in economic costs. At the present time, about one half of our crude oil production is burned either as crude oil or as fuel oil to generate steam and heat—the remainder is used as kerosene, gasoline, lubricating oil, etc.

"Up until thirteen years ago, the amount of gasoline which could be produced was limited to the natural fraction of gasoline in the crude product, but the discovery of cracking processes, by which the heavier oils can be broken down into gasoline, has opened an entirely new vision as to the gasoline supply."[2]

Aside from its importance as a conservation measure, curtailment of crude oil production would reestablish the petroleum industry on a sound economic footing by converting the major portion of it into the higher-valued gasoline and reducing operating costs incidental to the production and handling of large quantities of crude, much of which now is disposed of in the form of low-value fuel oil.

CONSEQUENCES OF DECLINE IN FUEL OIL SUPPLY

With the present indications of ample crude oil supply and the possibilities of greater economy in gasoline consumption, no sudden decline of fuel oil is to be expected. A gradual decline in supply would cause a corresponding rise in price to a point representing the actual value of fuel oil in its most advantageous uses in competition with coal. A considerable volume of present consumption in uses for which the advantage of fuel oil are not so great would readily and quickly revert to coal. The factors that determine the persistency of fuel oil consumption are: the special advantages of fuel oil for certain uses; the possibility of greater economy and efficiency in the use of fuel oil; the fact that the consumer in some cases is also a producer of some form of energy; the availability and the relative

---

1 Report of the Federal Oil Conservation Board to the President of the United States, September, 1926, Part I, p. 1.
2 Op. cit., p. 10.

cost of substitute fuels; the degree to which the use has become established; and the cost of changing the equipment.

The most notable example of special advantage of fuel oil is in *marine use,* and here it combines with the increasing fuel efficiency attained by the Diesel engine. The convenience of oil fuel for *domestic and commercial heating* is largely responsible for the rapid increase in use for this purpose. In both of these uses the factor of relative cost of fuel is of less significance.

In *railroad consumption* the cost factor is more important. Railroads in the Illinois coal market area have been substantial consumers of fuel oil and have absorbed much of the local surplus of fuel oil at prices generally below the level of coal competition. Under a condition of scarcity and rising prices for fuel oil, a rapid decline in consumption and a reversion to coal could be expected. Consumption should decline most rapidly in the central states, where railroad consumption has had its most rapid expansion, with consequent benefit to the railroads.

In the case of the *oil industry itself,* the fact that fuel oil is available at the lowest price for the use of the company that produces it, without any selling or transportation costs, while the opposite is true if other fuel is purchased, is an important consideration.The use of coal as a refinery fuel is restricted to areas of low cost coal or to operations where a high grade of crude oil is used with a small output of fuel oil. In case of a serious shortage of fuel oil much of this consumption might be replaced by coal, where natural gas is not available, but only after most of the other industrial users had made the change and where the fuel oil was needed for a higher priced marine market.

The consumption of fuel oil by *public utilities* has declined with the wider utilization of natural gas and the increased use of powdered coal. A material decline of fuel oil consumption in this group may be expected in case of fuel oil shortage.

The use of fuel oil in manufacturing represents a large and varied group of consumers, much of which is the result of an effort to extend the market for fuel oil at low prices in competition with coal and would decline greatly in the event of a shortage in fuel oil supply. The bulk of the oil is used for industrial heating or power purposes for which coal could be substituted.

CHAPTER IV

NATURAL GAS FACTOR IN THE ILLINOIS COAL MARKET AREA

Although natural gas has been produced and consumed in Illinois since 1886[1] and has been an important source of fuel for several years in the states of Missouri and Kansas on the southern border of the Illinois coal market area, it is only since 1930 that its consumption within this area itself has risen to a point where it must be recognized as a serious competitor in the energy market. From a consumption of 7,108,400,000 cubic feet for all purposes, in 1921, it rose to 108,202,000,000 cubic feet in 1934. This latter figure represents approximately an equivalent of 4 million tons of coal.[2]

The rapid increase of consumption in the Illinois coal market area is of particular interest because of its direct competition with coal produced in the Interior coal basin. Tables 23 and 24 show that the domestic use practically doubled but that a still more rapid increase occurred in industrial consumption. Particular attention should be given to the amount included under "other industrial consumption." This includes fuel used in manufacturing, public utilities, petroleum refining and cement plants. In each of these groups of industries coal and fuel oil are also used as fuels and the introduction of gas is a direct competitor of these in the energy market.

CONSUMPTION OF GAS IN FIELD OPERATIONS

Consumption of gas in field operations (drilling, pumping, and operating gasoline recovery plants) has been confined principally to Illinois and Kansas oil producing fields. Consumption for this purpose has been relatively small and is showing a decline in both states since 1925. Curtailment of oil production combined with increasing efficiency in the utilization of gas in field power equipment is responsible for this decline. The use of natural gas in oil field operations may be considered as non-competitive with coal. In reality, it represents a new fuel outlet occasioned by the development of a new industry and does not disturb existing markets for coal. The outlet for natural gas in oil field operations is limited, however, and will most likely become stabilized or even decline with the stabilization of oil production. The rapid increase in the use of gas for industrial purposes in 1930 and 1931 becomes of significance, therefore, since it represents a direct competition with coal and fuel oil.

1 Bell, A. H., Natural Gas in the Eastern Interior Coal Basin; Geology of Natural Gas: a Symposium, Amer. Assoc. Pet. Geologists, 1935, pp. 813-842.

2 One ton of coal is considered the equivalent of 25,000 cubic feet of natural gas.

DISTRIBUTION OF NATURAL GAS IN THE ILLINOIS COAL MARKET AREA

In addition to local production in Illinois, natural gas enters the state through long distance pipe lines originating in the Monroe field, Louisiana, the Panhandle field of Texas, the Hugoton field of southwestern Kansas, and minor fields in Oklahoma and Kansas. Four distinctive areas of gas consumption may be recognized in the Illinois coal market area. They are:

1. The St. Louis district
2. Chicago
3. Cities of central Illinois
4. Nebraska-Iowa-southern Minnesota district.

From Monroe, Louisiana, a 22-inch pipe line carries gas to St. Louis, East St. Louis, and Alton. Population of the cities served by this line are as follows:

St. Louis	821,960
East St. Louis	74,347
Alton	30,151
Granite City	25,130
Total	951,588

The Hugoton field is connected by a 24-inch pipe line of the Panhandle Eastern Pipe Line Company with Indianapolis, Indiana, and enroute supplies cities in north central Missouri and central Illinois. The communities in these states served by this pipe line are:

In Illinois	*Population*
Jacksonville	17,747
Peoria	104,969
Peoria Heights	3,279
Pekin	16,129
East Peoria	5,027
Springfield	71,864
Decatur	57,510
Clinton	5,920
Urbana-Champaign	33,804
Danville	36,765
Total	353,014

In Missouri	*Population*
Boonville	6,435
Fayette	2,630
Fulton	6,705
Harrisonville	2,306
Macon	3,851
Mexico	8,290
Moberly	13,772
Total	43,389
Total Illinois and Missouri	396,403

Other communities in southwestern Missouri served by pipe line extensions from the Kansas and Oklahoma fields are Springfield, Carthage, Joplin, Neosho, Nevada, Kansas City, and St. Joseph. These communities are, however, practically outside of the competitive zone for Illinois coal.

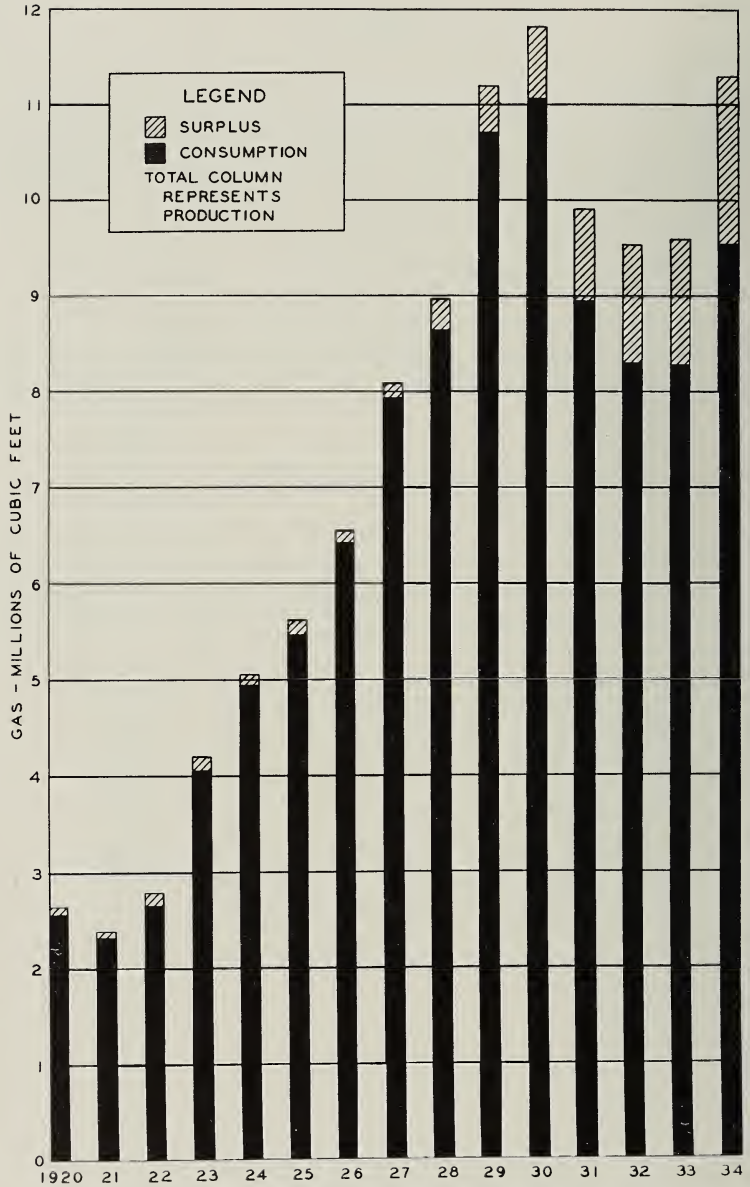

Fig. 3.—Natural Gas Production and Consumption in Kansas, Louisiana, Oklahoma, and Texas.

The Natural Gas Corporation of America has built a 24-inch pipe line from the Panhandle of Texas to Chicago. Only Chicago and suburbs are served by this line at present. The population of this metropolitan district is approximately 4,000,000.

The Northern Natural Gas Company taps the Panhandle field in Texas and serves or proposes extensions to existing pipe lines to serve 69 communities in eastern Nebraska, 38 communities in central Iowa, and 35 communities in Minnesota. LaCrosse, Wisconsin, would also be served by this system. Important cities now supplied by this system are Omaha and Lincoln, Nebraska, Council Bluffs, Sioux City, Des Moines, Fort Dodge and Mason City, Iowa, and Albert Lea, Minnesota. The lines now extend to Minneapolis and St. Paul, Rochester, and Winona, Minnesota.

In the western and central Dakotas, the Northern Minnesota Power Company supplies Williston, Bismark, and Rapid City from the gas field located near Miles City, Montana. This district is, however, outside of the limits of Illinois coal trade.

FACTORS UNDERLYING THE GROWTH OF IMPORTATION OF GAS INTO THE ILLINOIS COAL MARKET AREA

The record of increasing importation and consumption of natural gas in the Illinois coal market area described above raises the question as to the ultimate extent of utilization of this fuel and the effect of its introduction upon the competitive energy market. The answer to this question resolves itself into an analysis of potential supply of gas, extent and location of probable market outlets and the price at which this fuel can be delivered in the markets of the Upper Mississippi Valley.

Natural gas available to the Mississippi Valley region is produced in abundant quantities in the Mid-Continent, Gulf and Rocky Mountain fields and in limited quantities in the states of Kentucky, Tennessee, Indiana, Illinois, and Ohio, both as a by-product from oil wells and from fields which are primarily gas producers. The producers and consumers of energy materials in Illinois are particularly interested in conditions of supply and demand in Kansas, Louisiana, Oklahoma, and Texas from which states the natural gas consumed in the Illinois coal market area is obtained. In 1933, these four states operated 8997 gas wells and 126,650 oil wells the majority of which are also producers of enough gas to justify the efforts to save it. Production of gas in these states has increased enormously and, although consumption for field, industrial, and domestic use showed corresponding increases, nevertheless surplus gas available for export became more abundant. The comparative position of production, consumption and surplus for these states is shown in Table 25.

Table 25 and figure 3 disclose some interesting and significant characteristics of the natural gas industry in these states. Consumption has failed to keep pace with production with the result that in the fifteen-year period, the surplus of exportable gas has increased eleven fold. Consumption by uses within the area shows a rapid gain in industrial consumption, a gain proportional to production in field consumption, and a slower increase in domestic use. The question of interest is to what extent can the local market be expected to absorb the available supplies of natural gas and how much is available for export. One examination of trends in individual items of consumption may throw some light upon what may be expected in the immediate future.

Field use (for drilling, pumping, and operating gasoline recovery plants) has increased from 105,163 million in 1920 to 398,027 million cubic feet in 1934, or a ratio of 1:3.8. In the meantime, crude production in these states has increased from 287,091,000 bbls. to 522,377,000 barrels, or a ration of 1:1.8. Consumption of natural gas for field use has therefore increased more than the proportional output of crude petroleum. This may be due possibly to the substitution of gas for oil engines in field operations, increased pumping from wells and through pipe lines. That this increase will continue substantially is doubtful. While gasoline consumption is again showing an upward trend and, in 1935,

exceeded the previous high of 1929, it is not likely to continue the rate of increase experienced in the decade 1920-1929.

The rapid rise in industrial consumption also gives indications of deceleration when individual items of industrial use are examined. The most important of these in recent years has been carbon black. Consumption of natural gas, in these four states, in the manufacure of this product increased from 18,100 million cubic feet in 1920 to 222,910 million cubic feet in 1930. In that year the carbon black industry absorbed 39.4 per cent of the total industrial consumption. The explanation of this rapid rise is to be found in the nature of this particular industry. Carbon black is usually manufactured in districts where natural gas is produced in superabundance or in isolated localities which are too remote from pipe line systems to permit a connection with the producing well. The low value of the material (2.75 cents a pound in 1932) prohibits its manufacture from anything but gas with a low value at the well. Usually wherever pipe line connections can be made the value of the gas rises above the point where it is economical to continue its use in carbon black manufacture. For example, in 1932, an average of 1.44 pounds of carbon black valued at 2.75 cents was manufactured from 1000 cubic feet of gas, or about 4 cents worth of material per thousand cubic feet. After deducting manufacturing costs, it is evident that only a gas of low value can be used. The history of carbon black manufacture shows a migration from West Virginia to the mid-continent states as the new gas fields were opened and as increasing demand for heating purposes served to increase the value of gas in the older fields. The trend of natural gas utilization in carbon black manufacture by states, since 1920, is shown in Table 26.

The rapid increase in carbon black production resulted in a glutted market in 1930 with the result that production declined 29 per cent by 1933 in spite of a slight increase in demand. Combined domestic and foreign sales in 1933 totaled 374,644,000 pounds while stocks held by producers on December 31, 1933 amounted to 151,993,000 pounds. The resulting surfeit, together with opening up of new gas fields in Wyoming, Montana, and the Turner Valley in Canada, many of which have no pipe line connections and must find an outlet partially in carbon black manufacture, will tend to bring about a reduction in this industry in the Mid-Continent field. The opening of long distance pipe lines from the Monroe field in Louisiana, the Hugoton field in Kansas, and the Panhandle of Texas offer an outlet for the export of this surplus gas to the Upper Mississippi Valley.

[c] Included with Oklahoma.
[d] Other states.
[e] Not reported.

The third item in the consumption of natural gas for which data are separably available is the electric utility market. The rapid rise between 1920 and 1930 and the probable stabilization of consumption in this field is indicated by the data in Table 27.

TABLE 27.—CONSUMPTION OF FUEL BY ELECTRIC UTILITIES IN KANSAS, LOUISIANA, OKLAHOMA, AND TEXAS IN 1920, 1930, 1931, 1932, AND 1934

	1920	1930	1931	1932	1934	Per Cent in 1934
Coal, tons	961,124	1,116,316	935,444	818,549	955,001	
Fuel oil barrels	4,559,047	1,382,290	835,148	882,792	742,092	
Natural gas M cu. ft.	9,563,545	81,755,512	74,889,977	66,077,369	71,259,589	
FUEL OIL AND NATURAL GAS CONVERTED TO COAL EQUIVALENT						
Coal, tons	961,124	1,116,316	935,444	818,549	955,001	24.2
Fuel oil, coal equivalent[a]	1,086,000	329,000	198,000	210,190	176,688	4.4
Natural gas, coal equivalent[b]	382,400	3,270,000	3,000,000	2,643,100	2,850,383	71.4

[a] Fuel oil converted to coal equivalent on a basis of 4.2 barrels of oil per ton of coal.
[b] Natural gas converted to coal equivalent on a basis of 25,000 cubic feet of gas per ton of coal.

This table reveals the changes that have taken place in electric utility fuel consumption from 1920 to 1934. While coal consumption has remained practically constant, fuel oil has declined and natural gas has increased tremendously. Not only has fuel oil yielded to natural gas but practically all of the increase in total fuel consumption in 1930 and 1931 over the 1920 level is accounted for by natural gas. Continued increases in gas utilization in the electric utility market will depend upon a further displacement of coal and fuel oil, and increases of electric power output. Neither one of these factors is likely to be large enough to bring about a need for increased use of gas in substantial quantities.

SUMMARY OF NATURAL GAS CONSUMPTION IN THE LOCAL MARKET

The natural gas market in these states from which the Illinois coal market area obtains its supply of gas appears to be reaching the point of saturation. Nearly all cities and communities of 5000 inhabitants or more are now connected with natural gas lines. Consumption for domestic purposes has shown a considerable increase since 1927 but appears to be reaching a point of stabilization. Rapid increases in consumption for carbon black manufacture are the result of the combined factors of a decline of the industry in West Virginia, a pronounced growth in automobile tire manufacture in the past decade and in an output far in excess of market demand, especially in 1929 and 1930. Until surplus stocks of this material are sold and further production is necessary, this industry will probably be severely curtailed. This has already occurred in 1931 and 1932. When production is resumed, it will probably occur in states which have abundant supplies of gas without adequate markets for disposal through pipe line connec-

tions. Future production may be attempted in Wyoming, Montana, and Alberta, Canada. A program of curtailment in the crude oil industry will have a corresponding effect upon the consumption of natural gas for field operations. With a decrease in the rate of growth of gas consumption, the question of disposal of surplus gas becomes more critical. For this disposal six long distance outlets are provided, four of which enter into the Illinois coal market area.

MARKETING OF SURPLUS GAS FROM THE MID-CONTINENT FIELD

The potential reserves of natural gas appear to exceed by far the demands of the local market. The quantities of gas available in the United States are not measurable with the meagre data that is now on hand. "An estimate published recently credits the Kettleman Hills field in California with reserves of 37,500,000,000,000 cubic feet of natural gas, and the other developed fields of California with aggregate reserves of similar size. Enormous proven gas reserves also exist in the known fields of the Rocky Mountain States; of Kansas, Oklahoma, Texas, Louisiana, Arkansas, Mississippi, Kentucky, Ohio, and West Virginia; and other major areas appear to be in process of development in Michigan, in Pennsylvania and New York. What our undiscovered gas fields will yield, and what the deeper sands in some of the developed fields will produce is not now calculable, but I believe that the country's available gas reserves will amount to not less than 100,000,000,000,000 cubic feet and may greatly exceed 200,000,000,000,000 cubic feet."[1]

The minimum figure represents an equivalent of 4,000,000,000 tons of coal and the maximum figure more than 8,000,000,000 tons. If we credit half of the smaller figure to the Mid-Continent field, we arrive at a total of gaseous energy equivalent of 2,000,000,000 tons of coal available in this area and through long distance pipe line also available to the Illinois coal market area. Even allowing for the possibility that the above estimate should prove to be excessive, it appears that the gas reserves are ample to supply local needs in the Mid-Continent and provide a substantial quantity for the Illinois coal market area for some time to come.

The immediate concern, therefore, of the coal industry in Illinois is to find out at what rate the gas will be piped into this market territory. The maximum supply is, of course, limited by the carrying capacity of the pipe lines entering the market area.

Various qualifications and limitations, economic and technical, limit consumption below the potential quantities that the pipe lines can deliver. The critical factors in determining how much of the potential delivery capacity of the pipe lines will actually be marketed in this territory are:

(1) The annual capacity factor that will be built up.

(2) The fuel markets that can be obtained.

[1] Thom, W. T., Relationship of bituminous coal to oil and gas: Proceedings of the Third International Conference on Bituminous Coal, 1931, p. 84.

Annual capacity factor is here defined as the ratio of the average yearly load to the capacity of the pipe line. This capacity factor will be, theoretically, 100 per cent, if markets are available to consume the full capacity of the line each day of the year and 24 hours of the day. In actual operation such conditions do not exist.

The opposite extreme of this ideal condition is a condition where a pipe line serves only a house heating load. Demand would fluctuate widely from almost zero in the summer months to a peak load in the midst of winter. Even more unfavorable than the seasonal fluctuation would be the change in demand from day to day with the wide variations in temperature that are characteristic of climate in this area. A house heating load alone is generally recognized as uneconomical and an attempt is made to secure more balanced consumption by adding a lower price industrial load. Certain industries such as glass and pottery manufacure, printing, laundries, bakeries, or heat treatment operations where a gaseous fuel is either necessary or highly desirable, are ideal industrial consumers of gas. In some instances, it is possible for the gas producer to arrange with public utilities to purchase surplus gas on off-peak periods and in seasons of low domestic demand. This involves the necessity on the part of the public utility to maintain an auxiliary fuel plant burning either coal or fuel oil, and correspondingly enables them to secure low rates on gas. Low rates to intermittent consumers must therefore be offset by higher rates to domestic and small industrial consumers who must have continuous service.

SCHEDULE OF RATES FOR NATURAL GAS IN CHICAGO

In order to secure as large a capacity factor as possible, specially low rates are offered to industries which can make use of gas during the periods of low annual or daily demand. A comparison of rates for different types of services in Chicago will serve to illustrate this. Under the order of the Illinois Commerce Commission effective July 1, 1933, rates are prepared for twelve service classifications of which four are selected for purposes of illustration.

Service rates selected for illustration are:

(1) Residential service.
(2) Water heating service.
(3) Large volume service.
(4) Large volume interruptible service.

Sechedule of rates

Residential Service

Therms used in any one month	*Charge*
For the first 2 therms	58.0 cents
For the next 24 therms	15.8 cents per therm
For all over 26 therms	7.0 cents per therm

Water heating service

The rates under this classification for gas used during the months of October, November, December, January, February, March and April shall be:

25.0 cents per therm.

The rates under this classification for gas used during the months of May, June, July, August, and September shall be:

6.6 cents per therm.

Large Volume Service

Subject to certain limitations governing the quantity of gas to be supplied on Sundays and certain holidays, the rates for this service are as follows:

Therms used in any one month	*Charge*
For the first 1,000 therms or less	$107.50
For the next 4,000 therms	8.0 cents per therm
For the next 95,000 therms	5.0 cents per therm
For all over 100,000 therms	4.5 cents per therm

Large Volume Interruptible Service

Subject to conditions of plant location, consuming capacity of steam boilers, and uses of steam, stipulated by the gas company, together with the right to discontinue delivery temporarily upon short notice, and other conditions, the rate for this type of service is 12.5 cents per million British thermal units.

The purpose of the schedules in the low rate classifications is to increase the daily and yearly capacity factor by offering unusually low rates in off-peak periods and discouraging the use of gas in these classifications during the daily and annual peak load periods. Thus in the large volume interruptible service class, a public utility or other steam generating plant is offered surplus gas at an equivalent of about $3.00 a ton for 12,500 B. t. u. coal on an assumed basis of equal efficiency in combustion. If gas can be burned more efficiently than coal, a still greater advantage accrues to the former. The domestic consumer, meanwhile, pays a minimum of $17.50 for heat equivalent to a ton of coal at equal combustion efficiencies.

The extent to which industry in the Chicago area will take advantage of the rates now authorized is problematical.

CHAPTER V

WATER POWER IN THE ILLINOIS COAL MARKET AREA

Under modern conditions of power production the contribution of water power resources to the available power supply is practically limited to the generation of electrical energy. A small, but declining proportion of mechanical hydraulic power is still produced mainly in the older water power districts of the East but it is negligible in the Upper Mississippi Valley. The meagerness of water power resources in this latter area is evident from the limited contribution to the public utility output of these states and the small amounts that are considered potentially available for further development. An estimate of the United States Geological Survey places these potential resources at horsepower, distributed among the states as follows:

TABLE 28.—POTENTIAL WATER POWER RESOURCES OF THE STATES COMPRISING THE ILLINOIS COAL MARKET AREA [a]

State	Available 90 per cent of the time		Available 50 per cent of the time	
	Horsepower	Percentage of nation	Horsepower	Percentage of nation
Illinois	189,000	0.54	361,000	0.66
Wisconsin	285,000	0.82	480,000	0.87
Minnesota	203,000	0.58	401,000	0.73
Iowa	169,000	0.49	395,000	0.72
Missouri	67,000	0.19	152,000	0.27
North Dakota	82,000	0.23	193,000	0.35
South Dakota	63,000	0.18	110,000	0.20
Nebraska	183,000	0.53	342,000	0.62
Kansas	104,000	0.30	251,000	0.46
Total	1,345,000	3.86	2,685,000	4.88

[a] United States Geological Survey, Potential Water Power Resources of the United States, Mimeograph release, 1924.

If these resources were developed to the capacity indicated in the estimates above, available 90 per cent of the time, the potential output in kilowatt hours at 40 per cent capacity factor would be about 3,500,000,000 kilowatt hours. This is slightly more than the maximum output attained by existing water power plants in 1928. However, complete development of the physically potential water powers is not likely to occur. The economic feasibility of many of these small

and scattered waterpower sites is questionable in the face of competition from increasingly efficient steam stations. Moreover, many of the available waterpowers are in northern Wisconsin and Minnesota and in remote sections of the prairie states where transmission costs to consuming centers would add to the delivered cost of electric power.

An indication of the trend of water power development in the immediate future may be gained by an examination of the application before the Federal Power Commission, as reported in their eleventh annual report the year ending June 30, 1931 (Table 29).

TABLE 29.—DISTRIBUTION OF ACTIVE PROJECTS BY STATES, JUNE 30, 1931 [a]

	Number of projects	Primary horsepower	Installed capacity horsepower
Illinois	2	42,350	55,300
Wisconsin	4	28,941	67,420
Minnesota	4	19,290	48,200
Iowa	1	728	4,200
Missouri	6	105,330	483,000
North Dakota		0	0
South Dakota	3	1,000	1,600
Nebraska		0	0
Kansas		0	0
Total	20	197,639	659,720

[a] Eleventh Annual Report of the Federal Power Commission, 1931, p. 19.

Applications before the Federal Power Commission probably indicate the sites that, under present conditions, can be profitably developed. When completely installed, this added capacity can generate about 500,000,000 kilowatt hours at a 40 per cent capacity factor. This is one-sixth of the water power production in the maximum year of 1928 and would represent the displacement of about 400,000 tons of coal.

The actual hydro-electric power output since 1920 is given in Table 30.

Wisconsin, Iowa, Minnesota, and Illinois rank as most important. Appreciable gains in 1930 were registered only in Missouri with the opening of the new plant at Bagnell on the Osage River, while the growth in Wisconsin and Minnesota reflects the periodical development of small sites. The total output in 1933 was 19.5 per cent of all electric utility production in the states. Installed water power capacity in these states as of December 31, 1933, is given in Table 31.

TABLE 30.—COAL-EQUIVALENT OF HYDRO-ELECTRIC POWER PRODUCTION, 1920-1934

Year	Hydro-electric power[b] output in K. W. Hrs. (in thousands)	Pounds of coal per K. W. Hrs.	Coal equivalent (in thousands of tons)
1920	1,814,106	3.0	2,721

CHAPTER VI

ENERGY MARKET IN THE ELECTRIC UTILITY INDUSTRY

FUEL CONSUMPTION IN THE ELECTRIC UTILITY INDUSTRY

The statistical summary of the public utility fuel market for 1934 shows that 8,463,349 tons of coal, 810,192 barrels of fuel oil and 22,973,186 thousand cubic feet of natural gas were used by public utilities in the Illinois coal market area. If the fuel oil is converted into bituminous coal equivalent on a basis of 4.2 barrels of oil to a ton of coal and 25,000 cubic feet of natural gas are considered the equivalent of a ton of coal, the distribution of fuels used in the production of electrical energy is as follows:

	Tons	Per cent
Coal	8,463,349	88.4
Fuel oil	192,903	2.0
Natural gas	918,927	9.6
Total	9,575,179	100.0

In addition to the fuel-generated electrical energy there is also an output of approximately 16 per cent of the total by water power. The distribution of fuel and hydro-electrical energy for 1934 is given in Table 32.

The outlook for the coal market among public utilities is conditioned upon a complex and interlocking group of factors, the principal ones of which may be enumerated as follows:

(1) Development of potential water power sites.
(2) Trends in the use of fuel oil and natural gas.
(3) Advances in fuel economy.
(4) Future trend of electric power consumption.

POTENTIAL WATER POWER RESOURCES OF THE ILLINOIS COAL MARKET AREA

The potential growth of hydro-electric installations in the Illinois coal market area has been analyzed in a previous chapter and only the conclusions will be repeated here. On the basis of applications before the Federal Power Commission, the increase is estimated at 500,000,000 kilowatt hours, the approximate equivalent of 400,000 tons of coal at present levels of fuel efficiency. This is equal to 4 per cent of the present average of coal consumption. The most important of the projected installations are located in Missouri in which area the market for Illinois coal is of minor importance.

[a] Data compiled from Water Supply Paper 579, Power Capacity and Production in the United States, U. S. Geological Survey, 1928, and from the annual mimeographed reports on "Monthly and Annual Production of Electricity for Public Use in the United States, in 1927 to 1934."

[b] Data for 1920-1926 inclusive from Water Supply Paper 579, Power Capacity and Production in the United States, U. S. Geological Survey, Table 41, pp. 129-166, 1928. Data for succeeding years obtained from annual mimeographed reports of the Division of Power Resources of the United States Geological Survey.

NATURAL GAS AND FUEL OIL COMPETITION

Fuel oil and natural gas are only minor contributors to the fuel used by electric utility plants in this area. Indeed fuel oil has declined from a high figure of 2,332,148 barrels in 1922, representing 8.2 per cent of the total fuel consumption, to 769,867 barrels or 2.6 per cent of total fuel used. This decline has occurred mainly in Missouri and Kansas where competition from natural gas since 1928 has been a significant factor. These two states were also the largest users of fuel oil and accounted for 50 to 90 per cent of the total consumption in this area in different years. Consistent increases in fuel oil consumption have occurred in Illinois, Wisconsin, Minnesota, Iowa, the Dakotas and Nebraska, but the aggregate consumption is small and the increase is of small significance. (Table 33).

Natural gas consumption is important only in Iowa, Missouri, North Dakota, Nebraska, and Kansas. The principal effect of natural gas utilization has been a substitution for fuel oil rather than coal, with the possible exception of Kansas where coal consumption has also experienced a severe decline. It is significant, however, that the principal competition has been with Missouri, Kansas, and Oklahoma coal fields (Table 33).

The future trend in fuel oil utilization is probably toward a slow decline. The efforts of the oil industry to adjust production to market demand for motor fuels, coupled with an increasing percentage of gasoline recovery from the crude will tend to decrease the available supply of fuel oil. The decline will probably be slow but the public utility plants will probably be among the first to revert to coal utilization.

Natural gas consumption has shown a rapid increase since 1927 (Table 33) but is showing signs of becoming stabilized. The limits to natural gas consumption in the public utility field are probably fixed by the sizes of the market in or near the producing fields where gas is cheap. In the markets remote from the producing fields, the delivered cost of natural gas necessitates confining it to the higher priced markets such as domestic consumption or specialized industries requiring gaseous fuel in the process. Occasionally, natural gas may be used by public utilities in off-peak periods but this has not become an important factor.

FUEL EFFICIENCY

Of especial interest to the coal producer is the trend toward increased economy in fuel utilization. Efficiency in fuel utilization has made astonishing advances since 1902, when the average coal consumption per kilowatt-hour of electricity was 6.6 pounds. By 1920 the consumption was cut to 3.56 pounds in the Illinois coal market area and each year thereafter it steadily declined. The record from 1920 to 1932 is shown in Table 34. A brief calculation will show that the quantity of fuel used in 1932 on a basis of 1920 performance, would have been 18,000,000 tons or an excess of 10,000,000 tons over the actual consumption.

The question naturally arises: To what extent will increasing economy effect further reduction in the coal requirements per kilowatt-hour? Achievements of 1 pound per kilowatt hour or better have been recorded by large central stations. The Columbia station of the Columbia Power Company on Ohio River below Cincinnati achieved a record of 1 kilowatt-hour of 12,495 B. t. u.'s, or somewhat less than a pound of high grade bituminous coal. This fuel economy is accomplished by improvements in the design of power machinery, as well as in the method of firing under boilers. Higher pressures and temperatures, larger power units, mechanical stoking, and the use of powdered coal have been the chief contributing elements toward greater fuel economy.

The attainments of a large modern power plant cannot, of course, be achieved on the average. Many small power plants exist which cannot take advantage of heat economizers, mechanical stokers or high-pressure boilers. This is particularly true in the smaller cities of the agricultural sections where the size of the stations is sharply limited by market conditions. The present level of 1.6 pounds per kilowatt hour in the Illinois coal market area will be gradually reduced as new stations replace obsolete units and consolidations are effected, but from now the reduction will be slow. If an average level of 1.5 pounds per kilowatt hour be achieved eventually, it would mean a difference of about 1,300,000 tons of coal for an output of electricity equal to that of 1934.

FUTURE TREND OF THE ELECTRICAL MARKET

The demand for electric power increased at an average rate of 10 per cent in the decade 1920 to 1929. This period was characterized by (1) extensive replacement of private steam, hydraulic and steam-electric power plants in the manufacturing industries by purchased power and (2) rapid enlargement of the domestic market both in the number of customers served and the kilowatt-hour consumption per customer.

In the manufacturing industries, electrification has made continued progress, as illustrated by the figures below, based on Census data pertaining to total horsepower used.

	1914	1919	1929
	Per cent	*Per cent*	*Per cent*
Operated by purchased power	14.3	26.6	38.2
Individually generated power	18.1	19.2	22.4
Total electrification	32.4	44.8	60.6
Mechanical power	67.6	55.2	39.4
Total	100.0	100.0	100.0

[a] Data compiled from Water Supply Paper 579, Power Capacity and Production in the United States, U. S. Geological Survey, 1928, and from the annual mimeographed reports on "Monthly and Annual Production of Electricity for Public Use in the United States" in 1927, 1928, 1929, 1930, and 1931.

In the domestic field the use of electricity has grown rapidly since 1917. The introduction of electricity into the home occurred in 1882 and showed a moderate growth to 1917 when 24 per cent of homes were supplied with electricity. The decade following 1917 witnessed a more rapid growth, the number of electrified homes increasing from 24 per cent of the total in 1917 to 63 per cent in 1927. By 1929, 70 per cent of the total number of homes were electrified, and it is estimated that 10 per cent more are within reach of transmission lines.

The rapid growth of the past decade cannot be expected to continue. In 1930, 1931, and 1932 a recession of electric power output occurred from the high level of 1929, amounting to 2 per cent in 1930, 7 per cent in 1931 and 16 per cent in 1932. The recession continued into 1932 until the middle of the year when reviving industrial activity reversed the trend. This decrease, the direct result of the severe industrial depression, is remarkably small when compared with the decline of production in manufacturing and transportation. The staying power of the electric power industry is accounted for partly by an increasing domestic load in spite of depressed industrial conditions. The expected gradual return of industrial production will eventually bring the electric power output to its previous high levels and, as electric service is extended, may be expected to surpass the past records. A rate of expansion comparable to the 1920-29 decade is not to be anticipated, however. Rural extensions will be limited since most of the agricultural population is widely distributed and the potential market is too small to warrant an investment in distributing lines. Electrification of industry has been largely accomplished and further addition will be slow. In the domestic market, electrification of homes has reached a point that indicates a slower rate of expansion. The period is rapidly approaching when the growth of new business for household lighting will be limited to the annual increase in the number of families. An expansion of electric power consumption above this annual growth can be brought about only by an increase in the number of appliances used in the homes. To what extent this will offer an outlet for an expanding electric market cannot be determined.

SOURCES OF ELECTRIC UTILITY COAL

In Table 35 is given the origin of coal used by the electric utilities of the Illinois coal market area. This table discloses, first of all, the importance of local coal in the electric utility market. In Illinois, for example, 81 per cent of the coal used in the Chicago district, including Lake County, Indiana, and in other Illinois, is obtained from Illinois sources. In Iowa and Missouri more than half of the coal is obtained from the local fields west of Mississippi River, and practically all of the rest from the Eastern Interior fields of Illinois, Indiana, and Western Kentucky. The latter state, in particular, is an important contributor of coal to its immediate neighbors north and west. Appalachian coal becomes important only in the states comprising the Lake

TABLE 35.—SOURCES OF COAL USED BY ELECTRIC UTILITIES IN 1928, IN NET TONS[a]

[a] Sources of Coal and Types of Stokers and Burners used by electric public utility power plants: A report of the Institute of Economics in co-operation with the United States Geological Survey, by W. H. Young, pp. 75-77.

Dock Territory. This is particularly true of Wisconsin which obtains about 90 per cent of its coal from the Appalachian fields. This is explained, no doubt, by the fact that 80 per cent of the coal used by electric utilities in Wisconsin is consumed in counties bordering lakes Michigan and Superior. The proportion of Appalachian coal used by the electric utilities in Minnesota is not as high as Wisconsin, being about 55 per cent in 1928. Most of this is consumed in the Twin City and Duluth districts, both of which are closely connected with lake transportation.

OTHER FACTORS AFFECTING THE SOURCE OF ELECTRIC UTILITY COAL

The demand for coal by electric utilities is widely scattered, yet the bulk of it is concentrated in the largest centers of population and industry. In the Illinois coal market area, the following factors must be given consideration in the present and future distribution of demand:

(1) Location of water power resources.
(2) Effect of fuel oil and gas competition.
(3) Availability of adequate condensing water.
(4) Location of power consuming centers.

Power consuming centers or districts which consumed approximately 70 per cent of the coal used by electric utilities in the Illinois coal market area in 1929, in the order of their importance were as follows:

Chicago district; Lake, Cook, Will counties and Lake County, Indiana	4,261,310
St. Louis district; Madison and St. Clair counties, Illinois, and St. Louis County, Missouri	1,147,888
Eastern Wisconsin; Racine, Milwaukee, Ozaukee, Sheboygan, Manitowoc, Brown, Fond du Lac, and Washington counties	782,459
Kansas City–St. Joseph district; Jackson and Buchanan counties, Missouri, and Wyandotte County, Kansas	711,934
Peoria; Peoria and Tazewell counties	558,859
Twin Cities district; Hennepin and Ramsey counties	518,697
Southern Wisconsin-northern Illinois district; Winnebago County, Illinois; Rock and Dane counties, Wisconsin	185,560
Rock Island County	114,277
Total	8,280,984
Total in the Illinois coal market area	11,631,406

In each instance, except southern Wisconsin, the power plants supplying these markets are located near large available supplies of condensing water. The importance of this factor arises out of the fact that from 400 to 700 tons of cooling water for each ton of coal consumed is necessary for the economical operation of a power plant. This has stimulated the concentration of power plants in locations where water in unlimited quantities is available. Since the survey of coal consumption in 1929, additional water front stations are being erected in Ozaukee and Sheboygan counties, Wisconsin, which

further increases the localization of power plants on Lake Michigan. The low cost of coal transportation from the Appalachian fields over the Great Lakes to Wisconsin lake ports provides an added stimulus to the concentration of power sites along the western side of Lake Michigan. The combined factors of available water supply and cheap transportation will serve to continue the trend toward fewer and larger stations, the erection of transmission lines and the elimination of isolated interior stations.

CHAPTER VII

CONSUMPTION OF COAL IN THE MANUFACTURING INDUSTRIES

USE OF COAL IN THE MANUFACTURING INDUSTRIES

Coal is used in manufacturing in three different ways, namely: (1) to generate power by means of steam engines; (2) to produce heat that is applied directly to materials to transform them or to facilitate their manipulation; (3) to furnish material that enters into the actual composition of the product. The important industries using fuel in the latter manner are coke and gas.

Consumption of coal in the manufacturing industries increased with the expansion of industry until 1923, after which it declined, although industrial activity continued to increase thereafter until 1929. The trend of industrial activity by selected years from 1909 to 1929 is shown in Table 36.

TABLE 36.—GROWTH OF MANUFACTURING AND COAL CONSUMPTION, 1909–1929[a].

Year	Average number of wage earners, in thousands	Primary horsepower, in thousands	Value added by manufacture, in millions of dollars	Net tons of coal used, in thousands
1909	6,615	18,675	$ 8,529	177,853

1929	8,838	42,931	31,885	224,419

[a] Data from Department of Commerce, Bureau of the Census.

CAUSES OF DECLINE IN THE USE OF COAL

The causes of the decline of coal consumption in the face of increasing output in manufacturing industries are to be found in (1) the transfer of the power load to the electric utilities through the use of purchased power, (2) increased use of privately generated electric power in place of mechanical power, (3) improved practices in private steam plant operation, (4) saving of by-product heat, and (5) competition of fuel oil and natural gas.

[a] Census of Manufacture, 1929, Consumption of Fuel and Electrical Energy in Manufacturing Industries, pp. 13, 14.
[b] Fuel oil converted into equivalent of net tons of coal on a basis of 175 gallons of fuel oil to a ton of coal; manufactured gas on a basis of 50,000 cubic feet to a ton of coal; natural gas on a basis of 25,000 cubic feet to a ton of coal.

Electrification of manufacturing industries has made rapid progress in the past, increasing from 11 percent of the primary horsepower used in manufacturing in 1905 to 61 percent in 1927. Both privately developed power and purchased energy have increased at the expense of mechanical power—the latter more rapidly. Coal consumption in the manufacturing industries, therefore, has been curtailed in part by the transfer of energy demand to the electric utilities and in part by increased economy in coal use by conversion from mechanical power to electrical power within the plant itself. It is probable that the production of electricity in electric utility plants is accomplished with much greater fuel economy than in the case of electricity produced privately. Hence the transfer from the private generation of power, either mechanical or electrical, to the electric utility means not merely a transfer of coal consumption from one group of industries to another but an actual loss in the coal market; how much, it is difficult to say. Moreover, it may also mean a substitution of water power for coal power to a certain extent. Motors run by purchased power increased over 100 percent from 1919 to 1927, while steam power and internal combustion engines showed a loss.

The rapid rise of the rated horsepower of motors using purchased power must not be taken as an indication that either purchased power or total power consumption has risen in the same proportion. In many factories some of the motors are idle or are operating at considerably less than their rated capacity during a large part of the time, so that the combined rated capacity of all the motors greatly exceeds the amount of power delivered by them at any given moment.

The shifting trends of fuel consumption in the decade of 1919-1929 in manufacturing industries of the Illinois coal market area is shown in Table 35. Fuel oil and gas are converted to coal equivalent on a basis of 175 gallons of fuel oil per ton of coal and 25,000 cubic feet of natural gas to a ton of coal and 50,000 cubic feet of manufactured gas for the same. In this table coke is excluded from the Illinois total in view of the fact that this is a product derived from coal used in coke ovens, and, if included, would result in double counting.[1] Strictly speaking, this should also apply to manufactured gas which is a by-product of coke manufacture, but, in this case we are dealing with a fuel which in 1919 was largely wasted but by 1929 was being recovered and is therefore an addition to the total fuel supply.

An analysis of Table 37 showing consumption of fuels in manufacturing industries in two representative years, 1919 and 1929, discloses certain trends and developments that have vitally affected consumption of coal. In 1919 coal represented 78 per cent of fuel used by the manufacturing industries; a decade later, its position had fallen to 70 per cent, although the absolute

[1] Total exclusive of coke is not entirely justified since small quantities estimated at 250 thousand tons find their way into this market from Appalachian and Colorado ovens, and 1,800 tons come from Indiana, mostly to the Chicago district.

quantity had increased. During that interval, the use of fuel oil had almost doubled in quantity and gas (both natural and manufactured) increased from almost negligible quantities to 6 per cent of the total. This period of our industrial history was marked by a rapid expansion in petroleum output accompanied by an excessive output of fuel oil, the discovery and development of prolific gas producing fields in the Mid-Continent area, and rapid development in by-product coke manufacture and the recovery of by-product gases. Moreover, the end of the war period also marked the high level of coal prices, one of the most important factors in stimulating the search for and use of substitute fuels. Fuel competition was further intensified by remarkable advances in fuel economy. The effect has been, in the manufacturing industries, as among energy consumer groups, to flatten the curve of fuel demand in spite of an increasing industrial output and in the face of an increase in the availability of energy supplies.

FUEL OIL

Fuel oil made its most rapid advance in the early part of this decade reaching a point of stabilization about 1926. The bulk of fuel oil is used for industrial heating or power purposes for which coal could be substituted. Much of its represents the endeavor to extend the market for fuel oil at low prices in competition with coal and would decline greatly in the event of a shortage in fuel oil supply.

NATURAL GAS

Natural gas is important only in Kansas. The extension of long distance pipe lines to Chicago, St. Louis, Omaha and adjacent cities has affected mainly the consumption of other fuels in domestic heating and cooking, in the public utilities and in small manufacturing establishments. The high cost of gas transported several hundred miles from the field of origin will probably preclude its entry into the general manufacturing market.

MANUFACTURED GAS

The rise in manufactured gas is attributable to the improved methods of recovering, purifying, and utilizing what were formerly waste by-product gases, permitting the transfer of greatly increased quantities of gas from coke ovens and blast furnaces to steel works and rolling mills and to other steel-fabricating plants. Also part of the increase in 1929 is due to the inclusion of data for gases produced and consumed in the same plants, or in plants under the same ownership.

SUMMARY

It is probable that the greatest changes in the shifting competitive relationships of the fuels used in manufacturing have been accomplished in

the decade just closed. The determined efforts of the petroleum industry to hold production and refining within the limits of demand will bring about with it a stabilization or gradual decline in fuel oil supply. Higher prices for this fuel will result in a reversion to coal among the units of the manufacturing group. Cheap natural gas is limited to the areas of production and will be a factor only in the manufacturing industries of the Mid-Continent field where industrial activity is of secondary importance. Progress in by-product gas recovery has reached a point where further improvement will not materially increase the quantity of gas.

The trend in fuel consumption by the manufacturing group is not likely to rise above the 1929 level for some time in the future. The severe reverses of 1930, 1931, and 1932 reduced fuel consumption to a point where a substantial increase in output is necessary before a recovery equal to the 1929 market can occur.

CHAPTER VIII

RAILWAY FUEL CONSUMPTION

IMPORTANCE OF COAL IN RAILWAY TRANSPORTATION

The extent of railway mileage in the United States and the higher ratio of car miles to number of cars loaded as compared with other industrial nations results in an unusually large consumption of coal by American railroads. In 1929, for example, coal consumption by Class I railroads of the United States was 112,951,000 tons, plus fuel oil equivalent to 14,550,000 tons of coal while railroads of the United Kingdom consumed 14,900,000 tons of coal, and the German railroads, 16,600,000 tons.

The trend of railway coal consumption since 1917 has been downward. Several factors such as the use of fuel oil, increased efficiency of fuel utilization, variations in industrial activity and gradual changes in mode of transportation have affected this downward trend. In Table 39 is given the quantity of coal and the fuel oil equivalent of coal purchased by Class I Railroads from 1917 to 1932, together with data on the quantity of bituminous coal loaded for shipment and the ratio of railway fuel used to coal loaded for shipment.

The competitive effect of fuel oil is shown in the progressive increase in percentage of total fuel used by railroads.

DOWNWARD TREND OF RAILWAY FUEL CONSUMPTION

The progressive decline of fuel consumption by railroads, as shown in column (3) is a direct result of increasing efficiency of railway operation. Statistics of fuel consumption per 1,000 gross ton-miles, including locomotive and tender, are available back to 1920. In that year the average consumption was 173 pounds. Each succeeding year, except 1922, has shown improvement, the average for 1929 being 125 pounds. A similar record is to be observed in the passenger service. Fuel required to move a passenger car one mile in 1929 was 16.7 pounds whereas in 1923, the first year for which the figures are available, it was 20.7 pounds. Further economies were effected in the ensuing years, but the sharp decline in total fuel consumption from 1929 to 1932 was primarily the result of decreased railway traffic.

Decrease in fuel consumption was felt more severely by coal than by fuel oil. In fact the latter increased substantially to 1924 after which it remained

relatively stationary and showed a decline only after 1930. Even then the decline was relatively less than coal as shown by the increasing percentage of total fuel consumption in column (4) of Table 39.

Consumption of railway fuel also shows a close relationship to activity in the coal industry itself. Column (6) in Table 39 shows the relationship between fuel consumption by railroads and revenue coal loaded for shipment at the mines. Since 1926 the percentage has been fairly constant so that a large part of the decreasing consumption of railway fuel is directly attributable to a curtailed demand for coal.

Future trends in coal consumption by railroads must take into account:

(1) Factors affecting the future of railroad traffic.
(2) Future trend of fuel oil use.
(3) Future of railroad electrification.
(4) Trends in fuel efficiency.

Increase of railroad freight traffic has been proportionately less than the increase in commercial and industrial activity of the nation.

The explanation lies partly in the greater use of highways, gas, crude oil and gasoline pipe lines and inland waterways for the transportation of freight. Also, relocation of industries to get nearer to sources of raw materials or centers of consumption, or both, in order to save transportation expense, tends to diminish railway traffic. Increasing use of private automobiles and motor buses have made serious inroads on passenger traffic.

USE OF FUEL OIL

Ninety-five per cent of fuel oil consumed by railroads in the United States is delivered to railroads operating in two areas, the group of southern states, extending from Louisiana to California, and the group of northwestern states from Montana and Wyoming to the Pacific Coast. Since commercial deposits of coal are not readily accessible to railroads in the West, South Central, and Pacific states, except by a long freight haul, while ample supplies of fuel oil are available in the vicinity of the railroads, lines operating in these areas will continue to use fuel oil.

RAILROAD ELECTRIFICATION

With the exception of the electrification program of the large railroad terminals, and some of the short heavy traffic lines, no extensive new construction of this type is anticipated. Present consumption of electrical energy, together with the increase resulting from electrification projects now under construction, will effect only minor reductions in the annual coal bill.

1932	66,193	10,880	77,073	14.0	285,000	27.0

Column 1. Coal consumed by Class I Railroads of the United States, in thousands of net tons.
2. Coal equivalent of fuel oil consumed by Class I Railroads, in thousands of net tons. Fuel oil consumed is converted into equivalent coal fuel at a rate of 170 gallons of fuel oil to a ton of coal.
3. Total fuel consumption by Class I railroads of coal and coal equivalent of fuel oil, in thousand of net tons.
4. Fuel oil per cent of total fuel consumption.
5. Revenue coal loaded for shipment at the mines, in thousands of net tons.
6. Ratio of fuel used by railroads to revenue coal loaded for shipment at the mines.

TRENDS IN FUEL EFFICIENCY

Comparison of average performance with the best individual locomotive records indicates that progress in fuel economy made by railroads during the past decade has by no means reached its ultimate goal. Fuel efficiency is not merely a matter of increasing the thermal efficiency of the locomotive; it involves the management of operation of the railroad itself. Greater economy is obtained by supervision of engine maintenance, building train loads up to engine capacity, reducing idle engine time, treating boiler water to prevent scale, increasing tender capacity to reduce the number of coaling and water stops, and increasing the length of engine run. While this program of operating economy is running its course and the new level of efficiency is established, a stationary or even declining railroad coal market may be expected.

The Illinois coal industry has suffered a severe decline in coal deliveries to railroads. Data for 1917 and 1929 are available showing deliveries of coal to railroads by fields, indicating a drop in sales of Illinois coal from 33,696,513 tons in 1917 to 19,910,681 tons in 1929. Distribution of Illinois coal to the several railroad regions for that year is given in Table 38, p. 95.

CHAPTER IX

CONSUMPTION OF COAL IN THE DOMESTIC AND MISCELLANEOUS MARKETS[1]

Consumption of coal for domestic and commercial heating is the least known and most difficult to estimate among the several groups of coal consumers. By a process of elimination, a figure can be obtained for the consumption of coal in domestic heating and among the large number of small commercial and industrial consumers whose fuel requirements and purchasing habits do not differ markedly from those of the domestic user. A further deduction on the approximate consumption of domestic fuel can be obtained by estimates, based on data for single states or for specified years, of the per capita consumption of fuel for domestic use. Fortunately, accurate data of consumption, by states, of competitive fuels is available for coke in 1929, for fuel oil for the years 1926 to 1931, for anthracite in 1929, for fuel briquets in 1929-32 and for natural gas from the beginning of its use. With these figures as a basis, it is possible to evaluate, within a reasonable degree of accuracy, the relative position of bituminous coal in the total domestic energy market, and the trends in fuel consumption that are affecting this market.

CONSUMPTION OF ALL FUELS FOR DOMESTIC PURPOSES

In Table 40 is given the consumption of all fuels used for domestic purposes in 1929, the data for coal being estimated on a basis of 1.6 tons of fuel per capita per year.

Basis of calculations.—The quantity of bituminous coal used for domestic purposes in 1929 is obtained by multiplying the population of the area by 1.6—the calculated per capita consumption of coal or its equivalent in other fuels—and subtracting from this total the quantity represented by competitive fuels.

The results are shown in column (1) of Table 40. Two previous estimates of domestic fuel consumption are used as a basis of this calculation. In 1928, Tryon calculated the consumption of domestic fuel as 163,000,000 tons of which 136,000,000 tons was solid fuel and the equivalent of 27,000,000 tons

1 Includes heating large buildings other than factories, such as hotels, apartments, stores, offices, theatres, garages and service stations; also a number of other items that cannot be separated, such as waterworks, construction industry, threshing, public institutions, central heating plants, laundries, and very small industrial consumers not covered in the Census for Manufactures.

[c] 1930 figures.
[d] Converted on a basis of 4.2 barrels of fuel oil as equivalent to one ton of coal.

was represented by gaseous or liquid fuels[2]. This is an average of 1.36 tons of coal per capita for the United States. However, climatic differences must be taken into account in calculating fuel consumption in the different geographic regions of the United States. For example, in the states comprising the Illinois coal market area, a consumption of 32,328,199 tons of coal, both anthracite and bituminous is reported in 1917[3], or an average of 1.58 tons per capita. This figure probably represents all but a negligible part of the total fuel consumption during this year in view of the fact that fuel oil for domestic purposes was hardly more than an incidental factor, natural gas amounted to the equivalent of about 300,000 tons of coal in the Illinois coal market area, and coke consumption also was small, certainly not exceeding 400,000 tons in this area.

TREND OF COMPETITIVE FUELS

Fuel Oil.—The use of fuel oil in domestic furnaces is an important one and is still showing a substantial increase. Fuel oil is a by-product of the gasoline manufacturing industry and as such, the available supply is governed by conditions which have no direct relation to an elastic demand. Increasing demand for gasoline was accompanied by increasing quantities of fuel oil for which a market had to be found. These markets fell mainly into the following groups:

Oil company use
Marine use
Oil-burning railroad locomotives
Public utilities—gas and electric
Manufacturing industries
Commercial and domestic heating

In each of these groups, coal was the established fuel and replacement by fuel oil could be made mainly on a basis of competitive cost. Occasionally, liquid fuels offered advantages which warranted a price above the level of a comparable quantity of coal but, in the main, the price tended to adjust itself to the competitive level. Moreover, the supply of fuel oil increased each year to such an extent that the sellers of fuel oil were constantly confronted with the problem of extending their markets, so that substantial price increases at any time were out of the question.

Prices of domestic fuel oils followed in general the trend of wholesale and industrial fuel oil prices so that, in spite of a fairly wide spread for retailers' margins and local distribution costs, the retail price of domestic burning oil was low enough to compete successfully with coal.

---

2 Tryon, F. G., and Bennit, H. L., Coke and by-products: U. S. Bureau of Mines, Mineral Resources of the United States, 1928, Part II. Non-metals, p. 754.

3 Lesher, C. E., Coal—Part B, Distribution and Consumption; U. S. Bureau of Mines, Mineral Resources of the United States, 1917, Pt. II.

It must not be inferred that the encroachment of fuel oil in the domestic fuel market was due entirely to a competitive price level. In fact, the annual cost of heating a home is frequently higher with oil than with bituminous coal. The agressiveness of oil-burner salesmen, the appeal to convenience, and arguments of alleged greater cleanliness of fuel oil over coal were important factors in stimulating oil-furnace installations. The net result is that oil for domestic heating increased. The rate of growth for the Illinois coal market area is not available previous to 1926 but the general rate of growth for the country is shown in Table 41.

FUEL OIL CONSUMPTION IN THE ILLINOIS COAL MARKET AREA FOR DOMESTIC AND COMMERCIAL HEATING, 1926-1931

The rapid growth of fuel oil heating in the Illinois coal market area is shown in Table 42, giving consumption in commercial and domestic heating. This does not include light furnace oils for which statistics by states are not available. The most rapid growth is shown in the domestic group where the increase from 1926 to 1930 is at a ratio of 1:3.2. An examination, by states, shows that the most rapid growth occurred in the states of Illinois, Wisconsin, Minnesota, and Iowa. Those states are practically removed from the area of large scale competition from natural gas; also this is the area of high priced domestic coal so that it offered the most favorable territory for fuel oil originating at the refineries of the Chicago district. The increase in Wisconsin and Minnesota is particularly noticeable.

The question of immediate interest to the coal industry is the probable future trend of domestic consumption. The expansion of natural gas lines in eastern Kansas and Nebraska and western Missouri and Iowa may limit the further expansion of both fuel oil and coal in this part of the market area. Gas pipe lines to Chicago will replace a part of the domestic fuel oil and coal market in this city. The principal battle ground will be in the high-cost domestic fuel areas of the northern group of states. The competitive position of oil, bituminous coal, and anthracite will be determined by the factors

[a] Data from annual "National Survey of Fuel Oil Distribution", a report of the U. S. Bureau of Mines and published by the American Petroleum Institute.

of price, convenience, cleanliness, and marketing practices. The average price of various types of fuel in Chicago in 1932 where the competitive battle among the fuels is particularly keen was as follows:

Coal (per ton)	Price	
Anthracite		
Stove	$16.73	
Chestnut	15.30	
Bituminous		
High volatile	7.72	
Low volatile	11.41	
Run of mine	7.48	
Fuel oil (per gallon)	.06	
Natural gas (per therm)	.07	(after the first 26 therms)

The existing price relationships are not likely to be permanent or even of long duration. Bituminous coal prices can be fairly assumed to show no substantial increase in the future under existing competitive conditions among coal producing fields and districts. The present low price of fuel oil is by no means assured. In spite of the present large flowable potential represented by such fields as East Texas, Kettleman Hills (Middle Dome), Oklahoma City and Yates Pool, the combined effect of curtailment efforts on the part of the oil industry and the absence of major discoveries since 1930 point to an approaching scarcity and higher price for crude oil with its accompanying effect on fuel oil prices also.

Higher prices of fuel will not necessarily result in a return to coal burning equipment. Further improvements in oil-burning equipment and lower costs of domestic installations would favor continuance of this demand, although a decline in fuel oil supply might limit its further expansion. Moreover, the development of automatic domestic furnaces using prepared sizes of bituminous coal is giving these fuels more of the convenience factor.

The aggressive activities of oil burner salesmen, also, has been a factor in increased oil installations, a factor which coal dealers have ignored too long.

TRENDS IN NATURAL GAS CONSUMPTION

The sudden expansion of natural gas production and consumption in the Mid-Continent area and its distribution through long distance pipe lines to Chicago, Indianapolis, St. Louis, western and northern Iowa, eastern Nebraska, and western Missouri constitutes one of the most dynamic events in disturbing the markets of the older established fuels, both coal and fuel oil. The use of gas within or near the areas of production has long been established; long distance transportation began only with the discovery of huge reserves with prospects of long duration (notably the Hugoton fields in Kansas, the Amarillo field in north Texas, and the Monroe field in Louisiana) and a supply far in excess of the fullest possible market requirements of the Mid-Continent area itself. The effect upon the coal industry is disturbing

because the extent of its competition and the future trend is still largely an unknown factor. The general effect of natural gas invasion has been discussed in Chapter IV and the present analysis will be confined to the domestic fuel market.

Natural gas pipe lines now enter the Illinois coal market area through four major pipe line systems, namely, from the Texas Panhandle to Chicago; from the Hugoton Field in Kansas to Indianapolis with outlets to Springfield, Peoria, Clinton, Urbana, Danville, Decatur, and in central Missouri communities; from the Monroe field in Louisiana to St. Louis and Alton; and from the Texas Panhandle to a belt of communities in eastern Nebraska and central Iowa. A local field in eastern Montana serves the western Dakotas.

Domestic consumption of natural gas has shown a slow growth from 1920 to 1931 in this area as shown in Table 24, and averages 17,672,000,000 cubic feet, an equivalent of about 700,000 tons of coal. An examination of consumption by states, however, shows that the displacement of domestic coal by long distance pipe line gas is significant. Half of the domestic gas consumption is in Kansas which has long been supplied by local fields. The stationary behavior of consumption in this state indicates that the point of saturation of this fuel has been reached.

Previous to 1928, domestic gas consumption in Illinois depended largely on local gas supplies and, consequently, was declining. The introduction of gas through long distance pipe lines reversed the trend so that after 1929 there was a rapid increase in consumption. Outside of these three states, the most significant increase has been in western South Dakota which obtains its gas from Montana. Nebraska used gas for the first time in 1930 and the extent of this market is still problematical.

The place that natural gas will occupy in the domestic fuel market rests upon the factors of price, cleanliness and convenience, and the limitations imposed by the physical problems of distribution. The price of natural gas for domestic distribution must necessarily be high because of the nature of the market. First an elaborate distribution system is necessary involving a high overhead cost per unit of gas used, together with a relatively high clerical cost for handling the large number of small accounts. Secondly, the extreme seasonality of the household load imposes a burden of idle equipment upon the gas distribution company in the summer. These costs must necessarily be carried by the consumer, if the market is to be profitable to the gas distributors. Gas rates for residential service in Chicago, for example, are:

Therms[a] used in any one month	Charge	Cost of coal per ton at equivalent rates per therm
For the first 2 therms	58.0 cents	$162.40
For the next 24 therms	15.8 cents	44.24
For all over 26 therms	7.0 cents	19.60

[a]A therm is equivalent to 100,000 B. t. u's.

The second factor in limiting the extent of the domestic gas market is the physical limitation imposed by the distribution system. The rural dwelling is excluded by the prohibitive cost of gas transportation to a single dwelling. In urban communities, the nature of the gas load bears an important relation to the economic feasibility of gas utilization. If there is no industrial outlet to balance demand with the highly seasonal domestic load, the overall costs per unit of gas are higher and the price must be correspondingly high also. This in itself will impose limitations on the extension of gas into small urban communities in competition with coal or fuel oil.

Cleanliness and convenience are factors which would to a certain extent permit a higher price for gas and would have their greatest appeal to customers in the higher economic level.

ANTHRACITE IN ILLINOIS COAL MARKET AREA

The part occupied by anthracite in the Illinois coal market area can be analyzed briefly by an examination of Tables 43, 44, and 45. It is apparent that this type of fuel is losing ground in the area served by Illinois coal. Its original pre-eminent position is due to its excellence as a clean, smokeless fuel, coupled with a reasonably low pre-war cost. Moreover, consumer habits in Chicago, eastern Wisconsin, and the Twin Cities district in Minnesota, the principal anthracite consuming centers were strongly inured in the use of this fuel. Rising prices and the aggressiveness of competition, particularly fuel oil and coke, eventually served to weaken the hold of anthracite in this territory and it appears destined to recede to a negligible position. It will probably retain a considerable market in the lake shore counties of northern Illinois and eastern Wisconsin, and the northwest territory at the head of the Lake Superior docks, which can be reached by low lake freight rates. On the other hand, this market is practically closed to Illinois coal producers because of high all-rail freight rates from the southern fields to the lake shore territory. However, into interior Wisconsin and Minnesota, and in the states farther south and west, the costs of transportation on anthracite from lake ports mounts rapidly so that the competitive advantage of transportation in favor of eastern coals soon disappears.

FUEL BRIQUETS

Consumption of fuel briquets has shown a rapid increase in this country from 1924 to 1929 but their percentage of the total domestic fuel bill is so small that these increases are not significant. The record for the country as a whole since 1924 is shown in Table 46.

1929	1,212,415	.....	.....
1930	1,028,865	687,377	67
1931	688,258	433,308	63
1932	485,288	318,374	65
1933	529,162	340,765	64
1934	703,592	420,550	60

In the years 1930 to 1934, the Illinois coal market area accounted for about two-thirds of the total consumption and one-half of the total production. Other important producing and consuming centers are in Pennsylvania, Ohio, New Jersey, and Massachusetts. A list of plants operating in 1931 in the Illinois coal market area together with the type of raw material used and the location of the plant is given in Table 5 (p. 23).

Apparently briquetting plants and the briquet industry find their economic position in the areas of high priced domestic fuels and near sources of waste or by-product raw materials. In the lake dock coal trade, there is a considerable production of fines and screenings through degradation as a result of frequent handling.

This results in a degradation at the docks of from 5-6 per cent on the best grades of anthracite to 60 or even 70 per cent on the brittle Pocahontas.[5] These screenings are sold to different consumers, the price averaging from $5.50 to $6.00 a ton delivered.

The average selling price of briquets in the central states varies from $8.00 to $9.00 a ton. The largest item of expense in manufacture is raw material. An analysis of manufacturing costs per ton was compiled by the U. S. Bureau of Mines for 1927 at 16 briquetting plants resulting in the following figures:

Cost	Total	Per ton
Salaries	$ 149,598	$0.17
Wages	426,584	.47
Materials	4,609,988	5.09
Power and fuel used	236,411	.26
Total	5,422,581	5.99
Value of product	7,116,710	7.86
Value added by manufacture	1,694,129	1.87

[5] Vaile, R. S., and Pickett, V. G., Coal Distribution in the Twin Cities; University of Minnesota, Studies in Economics and Business, No. 2, June, 1932, p. 39.

To the per ton cost of $5.99 must be added additional charges for insurance, taxes, interest on the investment, and depreciation of the equipment. The average costs quoted above are probably somewhat lower than in the Wisconsin plants because of a higher cost of raw material for the latter. The briquet operator must work on a narrow margin of profit. The retail value of his product is governed by competitive conditions and will tend to follow more or less the price of prepared sizes of bituminous coal. With better preparation and improved stokers for the latter fuel, the competitive position of briquets is likely to become more difficult.

TABLE 47.—CONSUMPTION OF FUEL BRIQUETS IN THE ILLINOIS COAL MARKET AREA, 1930 to 1934

(In net tons)

State	1930	1931	1932	1933	1934

COKE AS A DOMESTIC FUEL

The use of coke as a domestic fuel has grown consistently and has suffered less in the years of severe business depression, 1930-1932, than its older competitor—anthracite. Consumption in 1929, the year selected for detailed distribution data is shown in Table 48.

TABLE 48.—CONSUMPTION OF COKE FOR DOMESTIC PURPOSES.

State	*Tons*
Illinois	1,026,575
Wisconsin	407,636
Minnesota	403,467
Iowa	63,820
Missouri	153,222
North Dakota	4,636
South Dakota	6,627
Nebraska	7,777
Kansas	2,970
Total, Illinois coal market area	2,078,730
Per cent of U. S. total	30.2
Total, United States	6,826,694

The unusually high proportion of the nation's domestic coke consumption within the boundaries of the Illinois coal market area is probably the outcome of an effort to find an acceptable substitute for the high cost anthracite. A similar concentration of consumption is observable with fuel briquets indicating that a moderate priced prepared domestic fuel with characteristics approaching the clean, smokeless qualities of anthracite can find a ready market in this area.

COMPETITION AMONG BITUMINOUS COALS FROM APPALACHIAN AND ILLINOIS FIELDS

Illinois coal producers of domestic coal grade meet competition not only from gas, fuel oil, anthracite, coke, and briquets, but, to a large measure from the prepared sizes of eastern bituminous coals. Data on total shipments of eastern coal by all-rail haul and over the lake docks are available but the specific quantity used for domestic heating is not known. The extent to which eastern coals are used is a resultant of the factors of consumer habits or preferences, dealers' preferences, extent of wholesale coal distribution in the important coal receiving and coal distributing centers of this market area, and comparative delivered costs. In this last item transportation costs play an important part and an analysis of transportation from representative competing fields in Illinois and the eastern states makes it possible to delimit more sharply the areas in which each has the advantage and areas where competition is keen.

In Table 14 are given freight rates on coal from three competing areas,[6] viz., southern Illinois, the high volatile fields of the Kenova-Thacker district, and the low volatile fields of the Pocahontas and Tug River districts. The latter are favorably regarded as domestic fuels.

An analysis of this table shows that the freight rate structure favors eastern coals in the markets north of Chicago on the eastern Wisconsin shore and in the Duluth-Superior district. In Chicago and the St. Paul-Minneapolis district transportation rates are almost comparable with a slight advantage to southern Illinois coal. In the interior cities of northern Illinois, Wisconsin, and Minnesota, the added freight rate on eastern coal from the lake docks brings the total cost of transportation considerably above the all-rail rate to these same localities from the southern Illinois fields. The line of demarcation between the areas in which eastern coal is dominant and in which Illinois coal can find a profitable outlet may be drawn roughly to include the lake shore tier of counties into the former area.

The dominant position of lake cargo coal in the lake dock territory is explained by an examination of Table 49. Counties bordering the lake in

[6] The freight rate on coal carried over the lakes includes loading charge of $.08 at the lower lake docks. Lake rates are figured at 50 cents to Chicago and Milwaukee and 40 cents to Duluth-Superior.

TABLE 49.—BITUMINOUS COAL CONSUMPTION IN THE LAKE SHORE COUNTIES OF NORTHERN ILLINOIS, EASTERN WISCONSIN, AND NORTHEASTERN MINNESOTA, 1929

County	Coal used, in net tons

Illinois consume nearly 50 per cent of the coal consumed by four important consumer groups; in Wisconsin, it is about 67 per cent. These counties lie in the area served by lake ports and which obtain their coal as cheap or more cheaply by lake transportation than is possible by all-rail haul from southern or southwestern Illinois. Although the distribution of lake cargo coal is not confined to the lake shore areas, nevertheless the bulk of the coal from this source is disposed of here. This leaves the remaining interior market the logical outlet for Illinois coal.

NATURE OF THE INTERIOR MARKET

Within the area thus delimited, the domestic coal market is complicated by competition from local coal supplies, a widening net work of natural gas lines, furnace and fuel oil, coke, and western Kentucky coal. Never before

have the number of types of fuels available for domestic use been so large nor has the potential supply been so abundant. Changing conditions of fuel supply have been accompanied by changes in consumer demand. The householder is becoming more exacting. He is examining the several fuels offered for domestic heating on a basis of

(a) Cost—including cost of fuel and heating equipment.
(b) Quality—heat value, ash content, cleanliness (smoke free and soot free properties).
(c) Convenience—automatic operation, ash removal and servicing of heating plants.

INDEX
